Part IV

Flows and Cuts

The following slides are partially based on slides by Kevin Wayne.

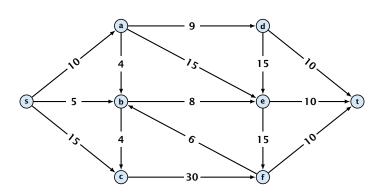

Flow Network

• directed graph G = (V, E); edge capacities c(e)

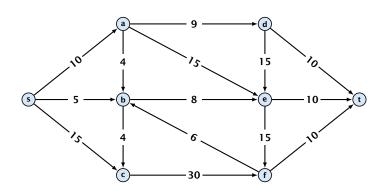

Flow Network

- directed graph G = (V, E); edge capacities c(e)
- two special nodes: source s; target t;

Flow Network

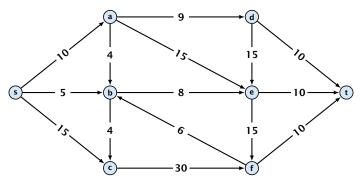

- directed graph G = (V, E); edge capacities c(e)
- two special nodes: source s; target t;
- no edges entering s or leaving t;

97/242

Flow Network

- directed graph G = (V, E); edge capacities c(e)
- two special nodes: source s; target t;
- no edges entering s or leaving t;
- at least for now: no parallel edges;

97/242

Definition 1

An (s, t)-cut in the graph G is given by a set $A \subset V$ with $s \in A$ and $t \in V \setminus A$.

Definition 1

An (s, t)-cut in the graph G is given by a set $A \subset V$ with $s \in A$ and $t \in V \setminus A$.

Definition 2

The capacity of a cut A is defined as

$$cap(A, V \setminus A) := \sum_{e \in out(A)} c(e) ,$$

where out(A) denotes the set of edges of the form $A \times V \setminus A$ (i.e. edges leaving A).

Definition 1

An (s, t)-cut in the graph G is given by a set $A \subset V$ with $s \in A$ and $t \in V \setminus A$.

Definition 2

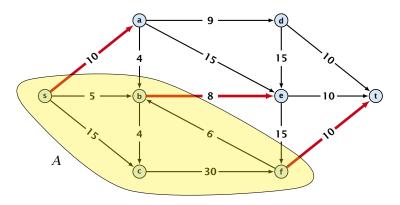

The capacity of a cut A is defined as

$$cap(A, V \setminus A) := \sum_{e \in out(A)} c(e) ,$$

where $\operatorname{out}(A)$ denotes the set of edges of the form $A \times V \setminus A$ (i.e. edges leaving A).

Minimum Cut Problem: Find an (s, t)-cut with minimum capacity.

Example 3

The capacity of the cut is $cap(A, V \setminus A) = 28$.

Definition 4

An (s,t)-flow is a function $f: E \rightarrow \mathbb{R}^+$ that satisfies

1. For each edge e

$$0 \le f(e) \le c(e)$$
.

(capacity constraints)

Definition 4

An (s,t)-flow is a function $f: E \rightarrow \mathbb{R}^+$ that satisfies

1. For each edge e

$$0 \le f(e) \le c(e)$$
.

(capacity constraints)

2. For each $v \in V \setminus \{s, t\}$

$$\sum_{e \in \text{out}(v)} f(e) = \sum_{e \in \text{into}(v)} f(e) .$$

(flow conservation constraints)

Definition 5

The value of an (s, t)-flow f is defined as

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(s)} f(e)$$
.

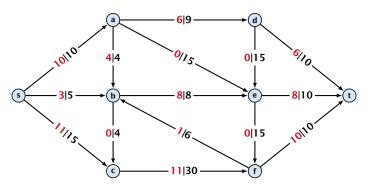

Definition 5

The value of an (s, t)-flow f is defined as

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(s)} f(e)$$
.

Maximum Flow Problem: Find an (s, t)-flow with maximum value.

Example 6

The value of the flow is val(f) = 24.

Lemma 7 (Flow value lemma)

Let f be a flow, and let $A \subseteq V$ be an (s,t)-cut. Then the net-flow across the cut is equal to the amount of flow leaving s, i.e.,

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(A)} f(e) - \sum_{e \in \operatorname{into}(A)} f(e)$$
.

val(f)

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(s)} f(e)$$

$$val(f) = \sum_{e \in out(s)} f(e)$$

$$= \sum_{e \in out(s)} f(e) + \sum_{v \in A \setminus \{s\}} \left(\sum_{e \in out(v)} f(e) - \sum_{e \in in(v)} f(e) \right)$$

$$val(f) = \sum_{e \in out(s)} f(e)$$

$$= \sum_{e \in out(s)} f(e) + \sum_{v \in A \setminus \{s\}} \left(\sum_{e \in out(v)} f(e) - \sum_{e \in in(v)} f(e) \right)$$

$$val(f) = \sum_{e \in out(s)} f(e)$$

$$= \sum_{e \in out(s)} f(e) + \sum_{v \in A \setminus \{s\}} \left(\sum_{e \in out(v)} f(e) - \sum_{e \in in(v)} f(e) \right)$$

$$= \sum_{e \in out(A)} f(e) - \sum_{e \in into(A)} f(e)$$

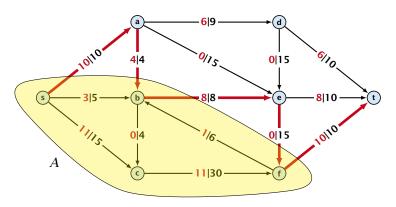

$$val(f) = \sum_{e \in out(s)} f(e)$$

$$= \sum_{e \in out(s)} f(e) + \sum_{v \in A \setminus \{s\}} \left(\sum_{e \in out(v)} f(e) - \sum_{e \in in(v)} f(e) \right)$$

$$= \sum_{e \in out(A)} f(e) - \sum_{e \in into(A)} f(e)$$

The last equality holds since every edge with both end-points in A contributes negatively as well as positively to the sum in Line 2. The only edges whose contribution doesn't cancel out are edges leaving or entering A.

Example 8

The net-flow across the cut is val(f) = 24.

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

$$\operatorname{val}(f) = \operatorname{cap}(A, V \setminus A).$$

Then f is a maximum flow.

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

$$\operatorname{val}(f) = \operatorname{cap}(A, V \setminus A).$$

Then f is a maximum flow.

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

$$\operatorname{val}(f) = \operatorname{cap}(A, V \setminus A).$$

Then f is a maximum flow.

Proof.

Suppose that there is a flow f' with larger value. Then

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

$$\operatorname{val}(f) = \operatorname{cap}(A, V \setminus A).$$

Then f is a maximum flow.

Proof.

Suppose that there is a flow f' with larger value. Then

$$cap(A, V \setminus A) < val(f')$$

Ernst Mavr. Harald Räcke

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

$$\operatorname{val}(f) = \operatorname{cap}(A, V \setminus A).$$

Then f is a maximum flow.

Proof.

Suppose that there is a flow f' with larger value. Then

$$cap(A, V \setminus A) < val(f')$$

$$= \sum_{e \in out(A)} f'(e) - \sum_{e \in into(A)} f'(e)$$

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

$$\operatorname{val}(f) = \operatorname{cap}(A, V \setminus A).$$

Then f is a maximum flow.

Proof.

Suppose that there is a flow f^{\prime} with larger value. Then

$$cap(A, V \setminus A) < val(f')$$

$$= \sum_{e \in out(A)} f'(e) - \sum_{e \in into(A)} f'(e)$$

$$\leq \sum_{e \in out(A)} f'(e)$$

106/242

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

$$val(f) = cap(A, V \setminus A).$$

Then f is a maximum flow.

Proof.

Suppose that there is a flow f^\prime with larger value. Then

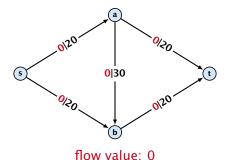

$$cap(A, V \setminus A) < val(f')$$

$$= \sum_{e \in out(A)} f'(e) - \sum_{e \in into(A)} f'(e)$$

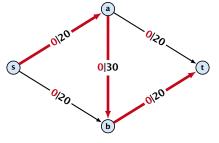

$$\leq \sum_{e \in out(A)} f'(e)$$

$$\leq cap(A, V \setminus A)$$

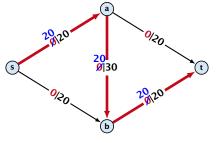

- **start with** f(e) = 0 everywhere
- find an s-t path with f(e) < c(e) on every edge
- augment flow along the path
- repeat as long as possible

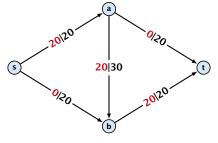

- **start with** f(e) = 0 everywhere
- find an s-t path with f(e) < c(e) on every edge
- augment flow along the path
- repeat as long as possible

- **start with** f(e) = 0 everywhere
- find an s-t path with f(e) < c(e) on every edge
- augment flow along the path
- repeat as long as possible

- repeat as long as possible

The Residual Graph

From the graph G = (V, E, c) and the current flow f we construct an auxiliary graph $G_f = (V, E_f, c_f)$ (the residual graph):

The Residual Graph

From the graph G = (V, E, c) and the current flow f we construct an auxiliary graph $G_f = (V, E_f, c_f)$ (the residual graph):

Suppose the original graph has edges $e_1 = (u, v)$, and $e_2 = (v, u)$ between u and v.

The Residual Graph

From the graph G = (V, E, c) and the current flow f we construct an auxiliary graph $G_f = (V, E_f, c_f)$ (the residual graph):

- Suppose the original graph has edges $e_1 = (u, v)$, and $e_2 = (v, u)$ between u and v.
- ▶ G_f has edge e_1' with capacity $\max\{0, c(e_1) f(e_1) + f(e_2)\}$ and e_2' with with capacity $\max\{0, c(e_2) f(e_2) + f(e_1)\}$.

The Residual Graph

From the graph G = (V, E, c) and the current flow f we construct an auxiliary graph $G_f = (V, E_f, c_f)$ (the residual graph):

- Suppose the original graph has edges $e_1 = (u, v)$, and $e_2 = (v, u)$ between u and v.
- ▶ G_f has edge e_1' with capacity $\max\{0, c(e_1) f(e_1) + f(e_2)\}$ and e_2' with with capacity $\max\{0, c(e_2) f(e_2) + f(e_1)\}$.

$$G_f = 0$$
 $\longrightarrow 0$ $\longrightarrow 0$

Definition 10

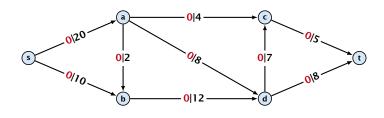

An augmenting path with respect to flow f, is a path from s to t in the auxiliary graph G_f that contains only edges with non-zero capacity.

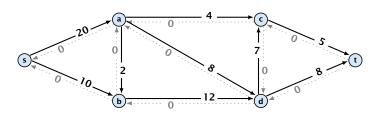

Definition 10

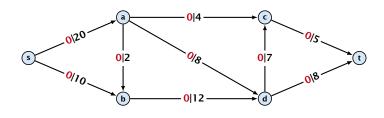

An augmenting path with respect to flow f, is a path from s to t in the auxiliary graph G_f that contains only edges with non-zero capacity.

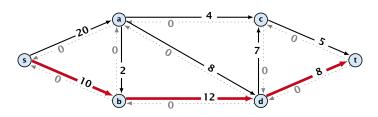

Algorithm 1 FordFulkerson(G = (V, E, c))

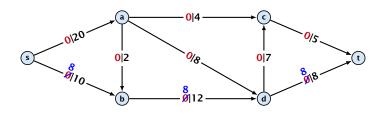

- 1: Initialize $f(e) \leftarrow 0$ for all edges.
- 2: **while** \exists augmenting path p in G_f **do**
- 3: augment as much flow along p as possible.

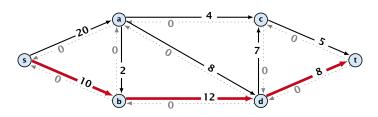

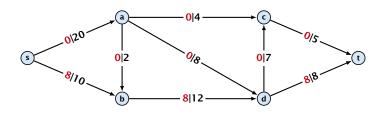

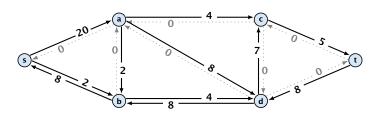

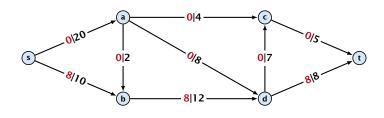

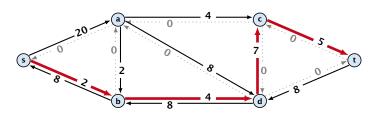

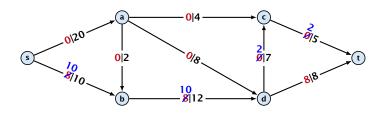

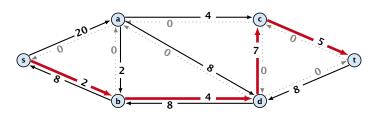

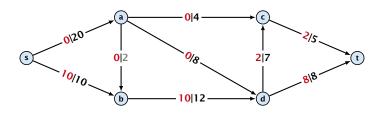

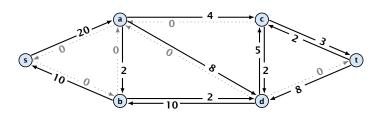

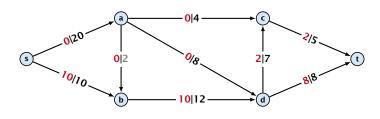

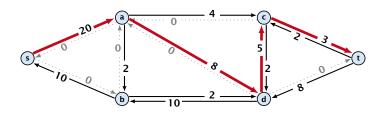

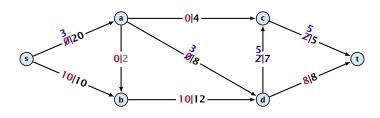

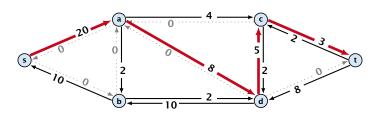

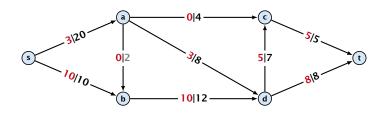

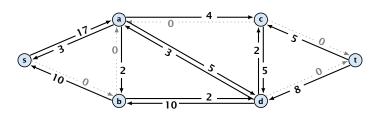

Theorem 11

A flow f is a maximum flow **iff** there are no augmenting paths.

Theorem 11

A flow f is a maximum flow **iff** there are no augmenting paths.

Theorem 12

The value of a maximum flow is equal to the value of a minimum cut.

Theorem 11

A flow f is a maximum flow **iff** there are no augmenting paths.

Theorem 12

The value of a maximum flow is equal to the value of a minimum cut.

Proof.

Let f be a flow. The following are equivalent:

1. There exists a cut A such that $val(f) = cap(A, V \setminus A)$.

Theorem 11

A flow f is a maximum flow **iff** there are no augmenting paths.

Theorem 12

The value of a maximum flow is equal to the value of a minimum cut.

Proof.

Let f be a flow. The following are equivalent:

- **1.** There exists a cut A such that $val(f) = cap(A, V \setminus A)$.
- 2. Flow f is a maximum flow.

Theorem 11

A flow f is a maximum flow **iff** there are no augmenting paths.

Theorem 12

The value of a maximum flow is equal to the value of a minimum cut.

Proof.

Let f be a flow. The following are equivalent:

- **1.** There exists a cut A such that $val(f) = cap(A, V \setminus A)$.
- 2. Flow f is a maximum flow.
- 3. There is no augmenting path w.r.t. f.

 $1. \Rightarrow 2.$

This we already showed.

 $1. \Rightarrow 2.$

This we already showed.

 $2. \Rightarrow 3.$

If there were an augmenting path, we could improve the flow. Contradiction.

$$1. \Rightarrow 2.$$

This we already showed.

$$2. \Rightarrow 3.$$

If there were an augmenting path, we could improve the flow. Contradiction.

- $3. \Rightarrow 1.$
 - Let f be a flow with no augmenting paths.

$$1. \Rightarrow 2.$$

This we already showed.

$$2. \Rightarrow 3.$$

If there were an augmenting path, we could improve the flow. Contradiction.

- $3. \Rightarrow 1.$
 - Let f be a flow with no augmenting paths.
 - Let A be the set of vertices reachable from s in the residual graph along non-zero capacity edges.

$$1. \Rightarrow 2.$$

This we already showed.

$$2. \Rightarrow 3.$$

If there were an augmenting path, we could improve the flow. Contradiction.

- $3. \Rightarrow 1.$
 - Let f be a flow with no augmenting paths.
 - Let A be the set of vertices reachable from s in the residual graph along non-zero capacity edges.
 - ▶ Since there is no augmenting path we have $s \in A$ and $t \notin A$.

val(f)

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(A)} f(e) - \sum_{e \in \operatorname{into}(A)} f(e)$$

$$val(f) = \sum_{e \in out(A)} f(e) - \sum_{e \in into(A)} f(e)$$
$$= \sum_{e \in out(A)} c(e)$$

$$val(f) = \sum_{e \in out(A)} f(e) - \sum_{e \in into(A)} f(e)$$
$$= \sum_{e \in out(A)} c(e)$$
$$= cap(A, V \setminus A)$$

$$val(f) = \sum_{e \in out(A)} f(e) - \sum_{e \in into(A)} f(e)$$
$$= \sum_{e \in out(A)} c(e)$$
$$= cap(A, V \setminus A)$$

This finishes the proof.

Here the first equality uses the flow value lemma, and the second exploits the fact that the flow along incoming edges must be 0 as the residual graph does not have edges leaving A.

Analysis

Assumption:

All capacities are integers between 1 and C.

Analysis

Assumption:

All capacities are integers between 1 and C.

Invariant:

Every flow value $f(\emph{e})$ and every residual capacity $\emph{c}_f(\emph{e})$ remains integral troughout the algorithm.

Lemma 13

The algorithm terminates in at most $val(f^*) \le nC$ iterations, where f^* denotes the maximum flow. Each iteration can be implemented in time $\mathcal{O}(m)$. This gives a total running time of $\mathcal{O}(nmC)$.

Lemma 13

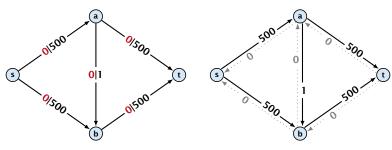

The algorithm terminates in at most $val(f^*) \le nC$ iterations, where f^* denotes the maximum flow. Each iteration can be implemented in time $\mathcal{O}(m)$. This gives a total running time of $\mathcal{O}(nmC)$.

Theorem 14

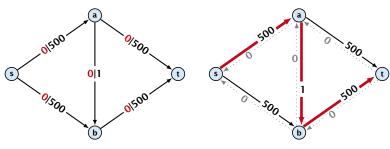

If all capacities are integers, then there exists a maximum flow for which every flow value f(e) is integral.

A Bad Input

. Then $r^{n+2} = r^n - r^{n+1}$.

flow value: $r^2 + r^3 + r^4$

Running time may be infinite!!!

We need to find paths efficiently.

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

- We need to find paths efficiently.
- ▶ We want to guarantee a small number of iterations.

Several possibilities:

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

Several possibilities:

Choose path with maximum bottleneck capacity.

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

Several possibilities:

- Choose path with maximum bottleneck capacity.
- Choose path with sufficiently large bottleneck capacity.

How to choose augmenting paths?

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

Several possibilities:

- Choose path with maximum bottleneck capacity.
- Choose path with sufficiently large bottleneck capacity.
- Choose the shortest augmenting path.

Lemma 15

The length of the shortest augmenting path never decreases.

Lemma 15

The length of the shortest augmenting path never decreases.

Lemma 16

After at most $\mathcal{O}(m)$ augmentations, the length of the shortest augmenting path strictly increases.

These two lemmas give the following theorem:

These two lemmas give the following theorem:

Theorem 17

The shortest augmenting path algorithm performs at most $\mathcal{O}(mn)$ augmentations. This gives a running time of $\mathcal{O}(m^2n)$.

These two lemmas give the following theorem:

Theorem 17

The shortest augmenting path algorithm performs at most $\mathcal{O}(mn)$ augmentations. This gives a running time of $\mathcal{O}(m^2n)$.

Proof.

• We can find the shortest augmenting paths in time $\mathcal{O}(m)$ via BFS.

These two lemmas give the following theorem:

Theorem 17

The shortest augmenting path algorithm performs at most $\mathcal{O}(mn)$ augmentations. This gives a running time of $\mathcal{O}(m^2n)$.

Proof.

- We can find the shortest augmenting paths in time $\mathcal{O}(m)$ via BFS.
- O(m) augmentations for paths of exactly k < n edges.

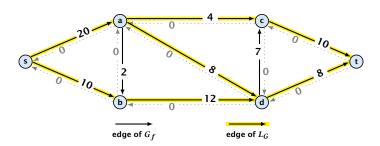

Define the level $\ell(v)$ of a node as the length of the shortest s-v path in G_f (along non-zero edges).

Define the level $\ell(v)$ of a node as the length of the shortest s-v path in G_f (along non-zero edges).

Let L_G denote the subgraph of the residual graph G_f that contains only those edges (u, v) with $\ell(v) = \ell(u) + 1$.

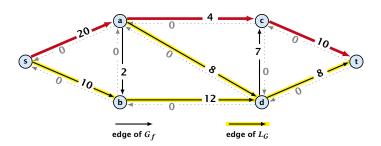

Define the level $\ell(v)$ of a node as the length of the shortest s-v path in G_f (along non-zero edges).

Let L_G denote the subgraph of the residual graph G_f that contains only those edges (u, v) with $\ell(v) = \ell(u) + 1$.

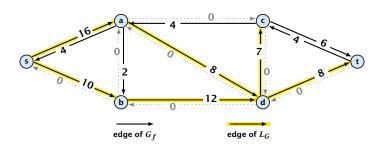

Define the level $\ell(v)$ of a node as the length of the shortest s-v path in G_f (along non-zero edges).

In each augmentation an edge is deleted from M.

Theorem 18

The shortest augmenting path algorithm performs at most $\mathcal{O}(mn)$ augmentations. Each augmentation can be performed in time $\mathcal{O}(m)$.

Theorem 18

The shortest augmenting path algorithm performs at most $\mathcal{O}(mn)$ augmentations. Each augmentation can be performed in time $\mathcal{O}(m)$.

Theorem 19 (without proof)

There exist networks with $m=\Theta(n^2)$ that require $\mathcal{O}(mn)$ augmentations, when we restrict ourselves to only augment along shortest augmenting paths.

Theorem 18

The shortest augmenting path algorithm performs at most $\mathcal{O}(mn)$ augmentations. Each augmentation can be performed in time $\mathcal{O}(m)$.

Theorem 19 (without proof)

There exist networks with $m = \Theta(n^2)$ that require O(mn) augmentations, when we restrict ourselves to only augment along shortest augmenting paths.

Note:

There always exists a set of m augmentations that gives a maximum flow (why?).

When sticking to shortest augmenting paths we cannot improve (asymptotically) on the number of augmentations.

When sticking to shortest augmenting paths we cannot improve (asymptotically) on the number of augmentations.

However, we can improve the running time to $\mathcal{O}(mn^2)$ by improving the running time for finding an augmenting path (currently we assume $\mathcal{O}(m)$ per augmentation for this).

We maintain a subset M of the edges of G_f with the guarantee that a shortest s-t path using only edges from M is a shortest augmenting path.

We maintain a subset M of the edges of G_f with the guarantee that a shortest s-t path using only edges from M is a shortest augmenting path.

With each augmentation some edges are deleted from M.

We maintain a subset M of the edges of G_f with the guarantee that a shortest s-t path using only edges from M is a shortest augmenting path.

With each augmentation some edges are deleted from M.

When M does not contain an s-t path anymore the distance between s and t strictly increases.

We maintain a subset M of the edges of G_f with the guarantee that a shortest s-t path using only edges from M is a shortest augmenting path.

With each augmentation some edges are deleted from M.

When M does not contain an s-t path anymore the distance between s and t strictly increases.

Note that ${\cal M}$ is not the set of edges of the level graph but a subset of level-graph edges.

M is initialized as the level graph L_G .

M is initialized as the level graph L_G .

Perform a DFS search to find a path from s to t using edges from M.

M is initialized as the level graph L_G .

Perform a DFS search to find a path from s to t using edges from M.

Either you find t after at most n steps, or you end at a node v that does not have any outgoing edges.

M is initialized as the level graph L_G .

Perform a DFS search to find a path from s to t using edges from M.

Either you find t after at most n steps, or you end at a node v that does not have any outgoing edges.

You can delete incoming edges of v from M.

Let a phase of the algorithm be defined by the time between two augmentations during which the distance between \emph{s} and \emph{t} strictly increases.

Let a phase of the algorithm be defined by the time between two augmentations during which the distance between s and t strictly increases.

Initializing M for the phase takes time $\mathcal{O}(m)$.

Let a phase of the algorithm be defined by the time between two augmentations during which the distance between s and t strictly increases.

Initializing M for the phase takes time $\mathcal{O}(m)$.

The total cost for searching for augmenting paths during a phase is at most $\mathcal{O}(mn)$, since every search (successful (i.e., reaching t) or unsuccessful) decreases the number of edges in M and takes time $\mathcal{O}(n)$.

Let a phase of the algorithm be defined by the time between two augmentations during which the distance between s and t strictly increases.

Initializing M for the phase takes time O(m).

The total cost for searching for augmenting paths during a phase is at most $\mathcal{O}(mn)$, since every search (successful (i.e., reaching t) or unsuccessful) decreases the number of edges in M and takes time $\mathcal{O}(n)$.

The total cost for performing an augmentation during a phase is only $\mathcal{O}(n)$. For every edge in the augmenting path one has to update the residual graph G_f and has to check whether the edge is still in M for the next search.

Let a phase of the algorithm be defined by the time between two augmentations during which the distance between s and t strictly increases.

Initializing M for the phase takes time $\mathcal{O}(m)$.

The total cost for searching for augmenting paths during a phase is at most $\mathcal{O}(mn)$, since every search (successful (i.e., reaching t) or unsuccessful) decreases the number of edges in M and takes time $\mathcal{O}(n)$.

The total cost for performing an augmentation during a phase is only $\mathcal{O}(n)$. For every edge in the augmenting path one has to update the residual graph G_f and has to check whether the edge is still in M for the next search.

There are at most n phases. Hence, total cost is $O(mn^2)$.

We need to find paths efficiently.

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

Several possibilities:

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

Several possibilities:

- Choose path with maximum bottleneck capacity.
- Choose path with sufficiently large bottleneck capacity.
- Choose the shortest augmenting path.

Intuition:

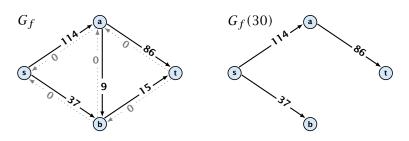

Choosing a path with the highest bottleneck increases the flow as much as possible in a single step.

- Choosing a path with the highest bottleneck increases the flow as much as possible in a single step.
- Don't worry about finding the exact bottleneck.

- Choosing a path with the highest bottleneck increases the flow as much as possible in a single step.
- Don't worry about finding the exact bottleneck.
- Maintain scaling parameter Δ .

- Choosing a path with the highest bottleneck increases the flow as much as possible in a single step.
- Don't worry about finding the exact bottleneck.
- Maintain scaling parameter Δ .
- $G_f(\Delta)$ is a sub-graph of the residual graph G_f that contains only edges with capacity at least Δ .

- Choosing a path with the highest bottleneck increases the flow as much as possible in a single step.
- Don't worry about finding the exact bottleneck.
- ▶ Maintain scaling parameter Δ .
- ▶ $G_f(\Delta)$ is a sub-graph of the residual graph G_f that contains only edges with capacity at least Δ .

```
Algorithm 1 maxflow(G, s, t, c)
 1: foreach e \in E do f_e \leftarrow 0;
 2: \Delta \leftarrow 2^{\lceil \log_2 C \rceil}
 3: while \Delta \geq 1 do
 4: G_f(\Delta) \leftarrow \Delta-residual graph
5: while there is augmenting path P in G_f(\Delta) do
6: f \leftarrow \text{augment}(f, c, P)
7: \text{update}(G_f(\Delta))
8: \Delta \leftarrow \Delta/2
 9: return f
```

Assumption:

All capacities are integers between 1 and ${\cal C}$.

Assumption:

All capacities are integers between 1 and C.

Invariant:

All flows and capacities are/remain integral throughout the algorithm.

Assumption:

All capacities are integers between 1 and C.

Invariant:

All flows and capacities are/remain integral throughout the algorithm.

Correctness:

The algorithm computes a maxflow:

• because of integrality we have $G_f(1) = G_f$

Assumption:

All capacities are integers between 1 and C.

Invariant:

All flows and capacities are/remain integral throughout the algorithm.

Correctness:

The algorithm computes a maxflow:

- because of integrality we have $G_f(1) = G_f$
- therefore after the last phase there are no augmenting paths anymore

Assumption:

All capacities are integers between 1 and C.

Invariant:

All flows and capacities are/remain integral throughout the algorithm.

Correctness:

The algorithm computes a maxflow:

- because of integrality we have $G_f(1) = G_f$
- therefore after the last phase there are no augmenting paths anymore
- this means we have a maximum flow.

Lemma 20

There are $\lceil \log C \rceil + 1$ iterations over Δ .

Proof: obvious.

Lemma 20

There are $\lceil \log C \rceil + 1$ iterations over Δ .

Proof: obvious.

Lemma 21

Let f be the flow at the end of a Δ -phase. Then the maximum flow is smaller than $\operatorname{val}(f) + m\Delta$.

Proof: less obvious, but simple:

Lemma 20

There are $\lceil \log C \rceil + 1$ *iterations over* Δ .

Proof: obvious.

Lemma 21

Let f be the flow at the end of a Δ -phase. Then the maximum flow is smaller than $\operatorname{val}(f) + m\Delta$.

Proof: less obvious, but simple:

▶ There must exist an s-t cut in $G_f(\Delta)$ of zero capacity.

Lemma 20

There are $\lceil \log C \rceil + 1$ iterations over Δ .

Proof: obvious.

Lemma 21

Let f be the flow at the end of a Δ -phase. Then the maximum flow is smaller than $\mathrm{val}(f) + m\Delta$.

Proof: less obvious, but simple:

- ▶ There must exist an s-t cut in $G_f(\Delta)$ of zero capacity.
- ▶ In G_f this cut can have capacity at most $m\Delta$.

Lemma 20

There are $\lceil \log C \rceil + 1$ iterations over Δ .

Proof: obvious.

Lemma 21

Let f be the flow at the end of a Δ -phase. Then the maximum flow is smaller than $val(f) + m\Delta$.

Proof: less obvious, but simple:

- ▶ There must exist an s-t cut in $G_f(\Delta)$ of zero capacity.
- In G_f this cut can have capacity at most $m\Delta$.
- This gives me an upper bound on the flow that I can still add.

134/242

Lemma 22

There are at most 2m augmentations per scaling-phase.

Lemma 22

There are at most 2m augmentations per scaling-phase.

Proof:

Let f be the flow at the end of the previous phase.

Lemma 22

There are at most 2m augmentations per scaling-phase.

Proof:

- Let f be the flow at the end of the previous phase.
- $ightharpoonup \operatorname{val}(f^*) \le \operatorname{val}(f) + 2m\Delta$

Lemma 22

There are at most 2m augmentations per scaling-phase.

Proof:

- Let f be the flow at the end of the previous phase.
- $ightharpoonup \operatorname{val}(f^*) \le \operatorname{val}(f) + 2m\Delta$
- **Each** augmentation increases flow by Δ .

Lemma 22

There are at most 2m augmentations per scaling-phase.

Proof:

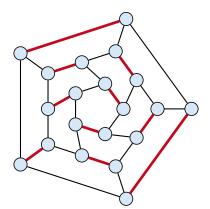

- Let f be the flow at the end of the previous phase.
- $ightharpoonup \operatorname{val}(f^*) \le \operatorname{val}(f) + 2m\Delta$
- **Each** augmentation increases flow by Δ .

Theorem 23

We need $\mathcal{O}(m \log C)$ augmentations. The algorithm can be implemented in time $\mathcal{O}(m^2 \log C)$.

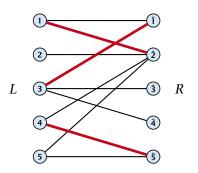

Matching

- ▶ Input: undirected graph G = (V, E).
- ▶ $M \subseteq E$ is a matching if each node appears in at most one edge in M.
- Maximum Matching: find a matching of maximum cardinality

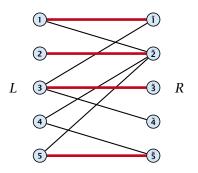

Bipartite Matching

- ▶ Input: undirected, bipartite graph $G = (L \uplus R, E)$.
- ▶ $M \subseteq E$ is a matching if each node appears in at most one edge in M.
- Maximum Matching: find a matching of maximum cardinality

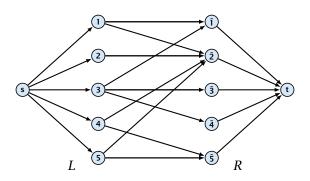

Bipartite Matching

- ▶ Input: undirected, bipartite graph $G = (L \uplus R, E)$.
- ▶ $M \subseteq E$ is a matching if each node appears in at most one edge in M.
- Maximum Matching: find a matching of maximum cardinality

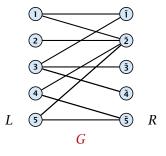

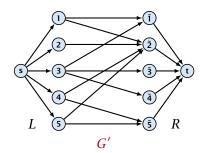

Maxflow Formulation

- ▶ Input: undirected, bipartite graph $G = (L \uplus R \uplus \{s, t\}, E')$.
- Direct all edges from L to R.
- Add source s and connect it to all nodes on the left.
- Add *t* and connect all nodes on the right to *t*.
- All edges have unit capacity.

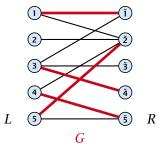

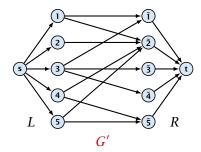

- Given a maximum matching M of cardinality k.
- Consider flow f that sends one unit along each of k paths.
- ightharpoonup f is a flow and has cardinality k.

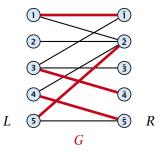

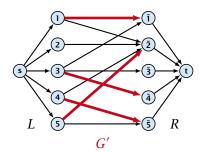

- Given a maximum matching M of cardinality k.
- Consider flow f that sends one unit along each of k paths.
- f is a flow and has cardinality k.

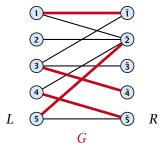

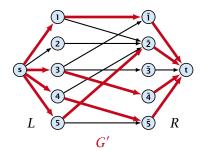

- Given a maximum matching M of cardinality k.
- ightharpoonup Consider flow f that sends one unit along each of k paths.
- ightharpoonup f is a flow and has cardinality k.

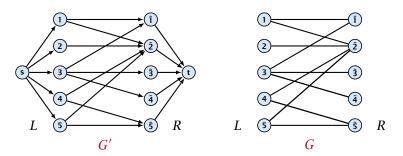

- Given a maximum matching M of cardinality k.
- ightharpoonup Consider flow f that sends one unit along each of k paths.
- f is a flow and has cardinality k.

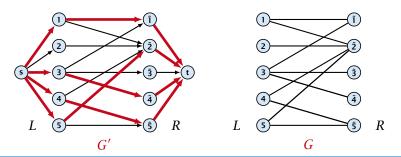

- Let f be a maxflow in G' of value k
- ▶ Integrality theorem $\Rightarrow k$ integral; we can assume f is 0/1.
- Consider M= set of edges from L to R with f(e) = 1.
- \blacktriangleright Each node in L and R participates in at most one edge in M.
- |M| = k, as the flow must use at least k middle edges.

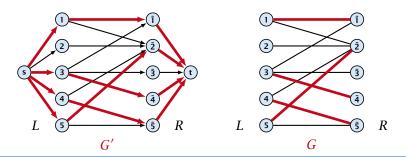

Max cardinality matching in $G \ge \text{value of maxflow in } G'$

- Let f be a maxflow in G' of value k
- ▶ Integrality theorem $\Rightarrow k$ integral; we can assume f is 0/1.
- ▶ Consider M= set of edges from L to R with f(e) = 1.
- **Each** node in L and R participates in at most one edge in M.
- |M| = k, as the flow must use at least k middle edges.

141/242

- Let f be a maxflow in G' of value k
- ▶ Integrality theorem $\Rightarrow k$ integral; we can assume f is 0/1.
- Consider M= set of edges from L to R with f(e) = 1.
- ▶ Each node in L and R participates in at most one edge in M.
- |M| = k, as the flow must use at least k middle edges.

12.1 Matching

Which flow algorithm to use?

- Generic augmenting path: $\mathcal{O}(m \operatorname{val}(f^*)) = \mathcal{O}(mn)$.
- Capacity scaling: $\mathcal{O}(m^2 \log C) = \mathcal{O}(m^2)$.
- Shortest augmenting path: $O(mn^2)$.

For unit capacity simple graphs shortest augmenting path can be implemented in time $\mathcal{O}(m\sqrt{n})$.

Baseball Elimination

team	wins	losses	remaining games			
i	w_i	ℓ_i	Atl	Phi	NY	Mon
Atlanta	83	71	_	1	6	1
Philadelphia	80	79	1	-	0	2
New York	78	78	6	0	_	0
Montreal	77	82	1	2	0	-

Which team can end the season with most wins?

- Montreal is eliminated, since even after winning all remaining games there are only 80 wins.
- But also Philadelphia is eliminated. Why?

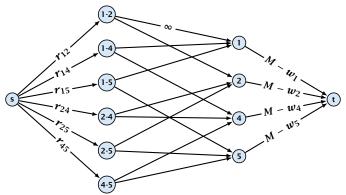

Baseball Elimination

Formal definition of the problem:

- ▶ Given a set S of teams, and one specific team $z \in S$.
- ▶ Team x has already won w_x games.
- ► Team x still has to play team y, r_{xy} times.
- Does team z still have a chance to finish with the most number of wins.

Baseball Elimination

Flow network for z = 3. M is number of wins Team 3 can still obtain.

Idea. Distribute the results of remaining games in such a way that no team gets too many wins.

Certificate of Elimination

Let $T \subseteq S$ be a subset of teams. Define

$$w(T) := \sum_{i \in T} w_i, \qquad r(T) := \sum_{i,j \in T, i < j} r_{ij}$$
 wins of teams in T remaining games among teams in T

If $\frac{w(T)+r(T)}{|T|}>M$ then one of the teams in T will have more than M wins in the end. A team that can win at most M games is therefore eliminated.

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} \gamma_{i,j}$.

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} \gamma_{i,j}$.

Proof (←)

Consider the mincut A in the flow network. Let T be the set of team-nodes in A.

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} r_{i,j}$.

Proof (←)

- Consider the mincut A in the flow network. Let T be the set of team-nodes in A.
- If for node x-y not both team-nodes x and y are in T, then x- $y \notin A$ as otw. the cut would cut an infinite capacity edge.

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} r_{i,j}$.

Proof (←)

- Consider the mincut A in the flow network. Let T be the set of team-nodes in A.
- If for node x-y not both team-nodes x and y are in T, then x- $y \notin A$ as otw. the cut would cut an infinite capacity edge.
- We don't find a flow that saturates all source edges:

$$r(S \setminus \{z\})$$

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} r_{i,j}$.

Proof (←)

- Consider the mincut A in the flow network. Let T be the set of team-nodes in A.
- If for node x-y not both team-nodes x and y are in T, then x- $y \notin A$ as otw. the cut would cut an infinite capacity edge.
- We don't find a flow that saturates all source edges:

$$r(S \setminus \{z\}) > \operatorname{cap}(A, V \setminus A)$$

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} r_{i,j}$.

Proof (←)

- Consider the mincut A in the flow network. Let T be the set of team-nodes in A.
- If for node x-y not both team-nodes x and y are in T, then x- $y \notin A$ as otw. the cut would cut an infinite capacity edge.
- We don't find a flow that saturates all source edges:

$$r(S \setminus \{z\}) > \operatorname{cap}(A, V \setminus A)$$

 $\geq \sum_{i < j: i \notin T \lor j \notin T} r_{ij} + \sum_{i \in T} (M - w_i)$

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} \gamma_{i,j}$.

Proof (←)

- Consider the mincut A in the flow network. Let T be the set of team-nodes in A.
- If for node x-y not both team-nodes x and y are in T, then x- $y \notin A$ as otw. the cut would cut an infinite capacity edge.
- We don't find a flow that saturates all source edges:

$$r(S \setminus \{z\}) > \operatorname{cap}(A, V \setminus A)$$

$$\geq \sum_{i < j: i \notin T \lor j \notin T} r_{ij} + \sum_{i \in T} (M - w_i)$$

$$\geq r(S \setminus \{z\}) - r(T) + |T|M - w(T)$$

A team z is eliminated if and only if the flow network for z does not allow a flow of value $\sum_{i,j \in S \setminus \{z\}, i < j} \gamma_{i,j}$.

Proof (⇐)

- Consider the mincut A in the flow network. Let T be the set of team-nodes in A.
- If for node x-y not both team-nodes x and y are in T, then x- $y \notin A$ as otw. the cut would cut an infinite capacity edge.
- We don't find a flow that saturates all source edges:

$$r(S \setminus \{z\}) > \operatorname{cap}(A, V \setminus A)$$

$$\geq \sum_{i < j: i \notin T \lor j \notin T} r_{ij} + \sum_{i \in T} (M - w_i)$$

$$\geq r(S \setminus \{z\}) - r(T) + |T|M - w(T)$$

► This gives M < (w(T) + r(T))/|T|, i.e., z is eliminated.

Proof (⇒)

Suppose we have a flow that saturates all source edges.

- Suppose we have a flow that saturates all source edges.
- We can assume that this flow is integral.

- Suppose we have a flow that saturates all source edges.
- We can assume that this flow is integral.
- For every pairing x-y it defines how many games team x and team y should win.

- Suppose we have a flow that saturates all source edges.
- We can assume that this flow is integral.
- For every pairing x-y it defines how many games team x and team y should win.
- ▶ The flow leaving the team-node x can be interpreted as the additional number of wins that team x will obtain.

- Suppose we have a flow that saturates all source edges.
- We can assume that this flow is integral.
- For every pairing x-y it defines how many games team x and team y should win.
- The flow leaving the team-node x can be interpreted as the additional number of wins that team x will obtain.
- ▶ This is less than $M w_X$ because of capacity constraints.

- Suppose we have a flow that saturates all source edges.
- We can assume that this flow is integral.
- For every pairing x-y it defines how many games team x and team y should win.
- ▶ The flow leaving the team-node x can be interpreted as the additional number of wins that team x will obtain.
- ▶ This is less than $M w_X$ because of capacity constraints.
- Hence, we found a set of results for the remaining games, such that no team obtains more than M wins in total.

- Suppose we have a flow that saturates all source edges.
- We can assume that this flow is integral.
- For every pairing x-y it defines how many games team x and team y should win.
- The flow leaving the team-node x can be interpreted as the additional number of wins that team x will obtain.
- ▶ This is less than $M w_X$ because of capacity constraints.
- Hence, we found a set of results for the remaining games, such that no team obtains more than M wins in total.
- Hence, team z is not eliminated.

Project selection problem:

Set P of possible projects. Project v has an associated profit p_v (can be positive or negative).

Project selection problem:

- Set P of possible projects. Project v has an associated profit p_v (can be positive or negative).
- Some projects have requirements (taking course EA2 requires course EA1).

Project selection problem:

- Set P of possible projects. Project v has an associated profit p_v (can be positive or negative).
- Some projects have requirements (taking course EA2 requires course EA1).
- Dependencies are modelled in a graph. Edge (u, v) means "can't do project u without also doing project v."

Project selection problem:

- Set P of possible projects. Project v has an associated profit p_v (can be positive or negative).
- Some projects have requirements (taking course EA2 requires course EA1).
- Dependencies are modelled in a graph. Edge (u, v) means "can't do project u without also doing project v."
- ▶ A subset *A* of projects is feasible if the prerequisites of every project in *A* also belong to *A*.

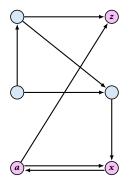

Project selection problem:

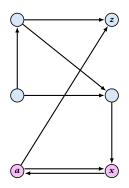

- Set P of possible projects. Project v has an associated profit p_v (can be positive or negative).
- Some projects have requirements (taking course EA2 requires course EA1).
- Dependencies are modelled in a graph. Edge (u, v) means "can't do project u without also doing project v."
- ▶ A subset *A* of projects is **feasible** if the prerequisites of every project in *A* also belong to *A*.

Goal: Find a feasible set of projects that maximizes the profit.

The prerequisite graph:

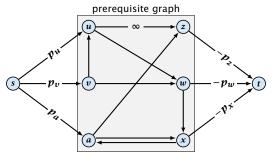

- \blacktriangleright {x, a, z} is a feasible subset.
- \triangleright {x, a} is infeasible.

Mincut formulation:

- Edges in the prerequisite graph get infinite capacity.
- Add edge (s, v) with capacity p_v for nodes v with positive profit.
- ► Create edge (v,t) with capacity $-p_v$ for nodes v with negative profit.

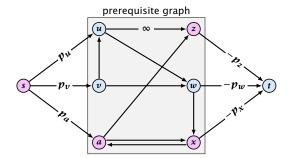

A is a mincut if $A \setminus \{s\}$ is the optimal set of projects.

A is a mincut if $A \setminus \{s\}$ is the optimal set of projects.

Proof.

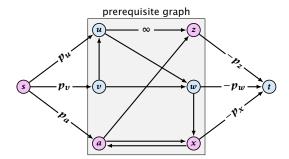

A is feasible because of capacity infinity edges.

A is a mincut if $A \setminus \{s\}$ is the optimal set of projects.

Proof.

- A is feasible because of capacity infinity edges.
- ightharpoonup cap $(A, V \setminus A)$

A is a mincut if $A \setminus \{s\}$ is the optimal set of projects.

Proof.

- ightharpoonup A is feasible because of capacity infinity edges.
- $ho \operatorname{cap}(A, V \setminus A) = \sum_{v} p_v + \sum_{v} (-p_v)$ $v \in \bar{A}: p_v > 0$ $v \in A: p_v < 0$ prerequisite graph

A is a mincut if $A \setminus \{s\}$ is the optimal set of projects.

Proof.

- ightharpoonup A is feasible because of capacity infinity edges.
- $v \in \bar{A}: p_v > 0$ $v \in A: p_v < 0$ $\sum_{v:p_v>0} p_v - \sum_{v\in A} p_v$ prerequisite graph

Definition 26

An (s,t)-preflow is a function $f:E\mapsto \mathbb{R}^+$ that satisfies

1. For each edge e

$$0 \le f(e) \le c(e) .$$

(capacity constraints)

Definition 26

An (s,t)-preflow is a function $f:E\mapsto \mathbb{R}^+$ that satisfies

1. For each edge e

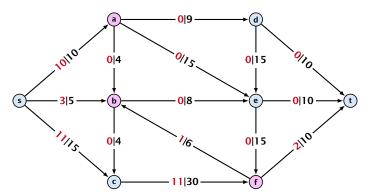

$$0 \leq f(e) \leq c(e) \ .$$

(capacity constraints)

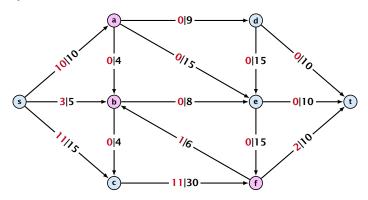

2. For each $v \in V \setminus \{s, t\}$

$$\sum_{e \in \text{out}(v)} f(e) \le \sum_{e \in \text{into}(v)} f(e) .$$

Example 27

Example 27

A node that has $\sum_{e \in \text{out}(v)} f(e) < \sum_{e \in \text{into}(v)} f(e)$ is called an active node.

Definition:

A labelling is a function $\ell: V \to \mathbb{N}$. It is valid for preflow f if

• $\ell(u) \le \ell(v) + 1$ for all edges (u, v) in the residual graph G_f (only non-zero capacity edges!!!)

Definition:

A labelling is a function $\ell: V \to \mathbb{N}$. It is valid for preflow f if

- $\ell(u) \le \ell(v) + 1$ for all edges (u, v) in the residual graph G_f (only non-zero capacity edges!!!)
- $\blacktriangleright \ell(s) = n$

Definition:

A labelling is a function $\ell: V \to \mathbb{N}$. It is valid for preflow f if

- $\ell(u) \le \ell(v) + 1$ for all edges (u, v) in the residual graph G_f (only non-zero capacity edges!!!)
- $\blacktriangleright \ell(s) = n$
- $ightharpoonup \ell(t) = 0$

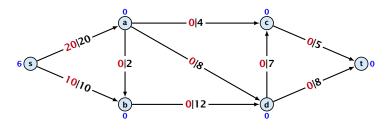

Definition:

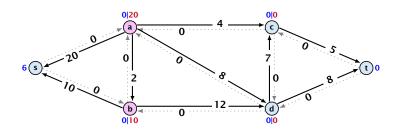

A labelling is a function $\ell: V \to \mathbb{N}$. It is valid for preflow f if

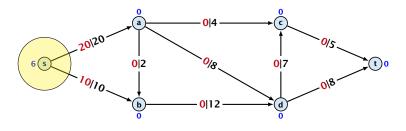

- $\ell(u) \le \ell(v) + 1$ for all edges (u, v) in the residual graph G_f (only non-zero capacity edges!!!)
- \blacktriangleright $\ell(s) = n$
- $\blacktriangleright \ell(t) = 0$

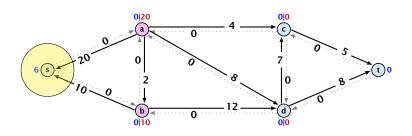

Intuition:

The labelling can be viewed as a height function. Whenever the height from node u to node v decreases by more than 1 (i.e., it goes very steep downhill from u to v), the corresponding edge must be saturated.

Lemma 28

A preflow that has a valid labelling saturates a cut.

Lemma 28

A preflow that has a valid labelling saturates a cut.

Proof:

▶ There are n nodes but n+1 different labels from $0, \ldots, n$.

Lemma 28

A preflow that has a valid labelling saturates a cut.

Proof:

- ▶ There are n nodes but n + 1 different labels from 0, ..., n.
- ▶ There must exist a label $d \in \{0, ..., n\}$ such that none of the nodes carries this label.

Lemma 28

A preflow that has a valid labelling saturates a cut.

Proof:

- ▶ There are n nodes but n + 1 different labels from 0, ..., n.
- ▶ There must exist a label $d \in \{0, ..., n\}$ such that none of the nodes carries this label.
- ▶ Let $A = \{v \in V \mid \ell(v) > d\}$ and $B = \{v \in V \mid \ell(v) < d\}$.

Lemma 28

A preflow that has a valid labelling saturates a cut.

Proof:

- ▶ There are n nodes but n + 1 different labels from 0, ..., n.
- ▶ There must exist a label $d \in \{0, ..., n\}$ such that none of the nodes carries this label.
- ▶ Let $A = \{v \in V \mid \ell(v) > d\}$ and $B = \{v \in V \mid \ell(v) < d\}$.
- ▶ We have $s \in A$ and $t \in B$ and there is no edge from A to B in the residual graph G_f ; this means that (A,B) is a saturated cut.

Lemma 28

A preflow that has a valid labelling saturates a cut.

Proof:

- ▶ There are n nodes but n + 1 different labels from 0, ..., n.
- ▶ There must exist a label $d \in \{0, ..., n\}$ such that none of the nodes carries this label.
- ▶ Let $A = \{v \in V \mid \ell(v) > d\}$ and $B = \{v \in V \mid \ell(v) < d\}$.
- ▶ We have $s \in A$ and $t \in B$ and there is no edge from A to B in the residual graph G_f ; this means that (A,B) is a saturated cut.

Lemma 29

A flow that has a valid labelling is a maximum flow.

Idea:

start with some preflow and some valid labelling

Idea:

- start with some preflow and some valid labelling
- successively change the preflow while maintaining a valid labelling

Idea:

- start with some preflow and some valid labelling
- successively change the preflow while maintaining a valid labelling
- stop when you have a flow (i.e., no more active nodes)

An arc (u,v) with $c_f(u,v)>0$ in the residual graph is admissible if $\ell(u)=\ell(v)+1$ (i.e., it goes downwards w.r.t. labelling ℓ).

An arc (u,v) with $c_f(u,v)>0$ in the residual graph is admissible if $\ell(u)=\ell(v)+1$ (i.e., it goes downwards w.r.t. labelling ℓ).

The push operation

Consider an active node u with excess flow

 $f(u) = \sum_{e \in \text{into}(u)} f(e) - \sum_{e \in \text{out}(u)} f(e)$ and suppose e = (u, v) is an admissible arc with residual capacity $c_f(e)$.

An arc (u,v) with $c_f(u,v)>0$ in the residual graph is admissible if $\ell(u)=\ell(v)+1$ (i.e., it goes downwards w.r.t. labelling ℓ).

The push operation

Consider an active node u with excess flow

 $f(u) = \sum_{e \in \text{into}(u)} f(e) - \sum_{e \in \text{out}(u)} f(e)$ and suppose e = (u, v) is an admissible arc with residual capacity $c_f(e)$.

We can send flow $\min\{c_f(e), f(u)\}$ along e and obtain a new preflow. The old labelling is still valid (!!!).

An arc (u,v) with $c_f(u,v)>0$ in the residual graph is admissible if $\ell(u)=\ell(v)+1$ (i.e., it goes downwards w.r.t. labelling ℓ).

The push operation

Consider an active node u with excess flow

 $f(u) = \sum_{e \in \text{into}(u)} f(e) - \sum_{e \in \text{out}(u)} f(e)$ and suppose e = (u, v) is an admissible arc with residual capacity $c_f(e)$.

We can send flow $\min\{c_f(e), f(u)\}$ along e and obtain a new preflow. The old labelling is still valid (!!!).

saturating push: $\min\{f(u), c_f(e)\} = c_f(e)$ the arc e is deleted from the residual graph

An arc (u,v) with $c_f(u,v)>0$ in the residual graph is admissible if $\ell(u)=\ell(v)+1$ (i.e., it goes downwards w.r.t. labelling ℓ).

The push operation

Consider an active node u with excess flow

 $f(u) = \sum_{e \in \text{into}(u)} f(e) - \sum_{e \in \text{out}(u)} f(e)$ and suppose e = (u, v) is an admissible arc with residual capacity $c_f(e)$.

We can send flow $\min\{c_f(e), f(u)\}$ along e and obtain a new preflow. The old labelling is still valid (!!!).

- ▶ saturating push: $min\{f(u), c_f(e)\} = c_f(e)$ the arc e is deleted from the residual graph
- ▶ deactivating push: $min{f(u), c_f(e)} = f(u)$ the node u becomes inactive

The relabel operation

Consider an active node \boldsymbol{u} that does not have an outgoing admissible arc.

The relabel operation

Consider an active node u that does not have an outgoing admissible arc.

Increasing the label of u by 1 results in a valid labelling.

The relabel operation

Consider an active node u that does not have an outgoing admissible arc.

Increasing the label of u by 1 results in a valid labelling.

► Edges (w, u) incoming to u still fulfill their constraint $\ell(w) \le \ell(u) + 1$.

The relabel operation

Consider an active node u that does not have an outgoing admissible arc.

Increasing the label of u by 1 results in a valid labelling.

- ▶ Edges (w, u) incoming to u still fulfill their constraint $\ell(w) \le \ell(u) + 1$.
- An outgoing edge (u, w) had $\ell(u) < \ell(w) + 1$ before since it was not admissible. Now: $\ell(u) \le \ell(w) + 1$.

Intuition:

We want to send flow downwards, since the source has a height/label of n and the target a height/label of 0. If we see an active node u with an admissible arc we push the flow at u towards the other end-point that has a lower height/label. If we do not have an admissible arc but excess flow into u it should roughly mean that the level/height/label of u should rise. (If we consider the flow to be water then this would be natural.)

Note that the above intuition is very incorrect as the labels are integral, i.e., they cannot really be seen as the height of a node.

Reminder

- In a preflow nodes may not fulfill conservation constraints; a node may have more incoming flow than outgoing flow.
- Such a node is called active.
- \triangleright A labelling is valid if for every edge (u, v) in the residual graph $\ell(u) \leq \ell(v) + 1$.
- An arc (u, v) in residual graph is admissible if $\ell(u) = \ell(v) + 1.$
- A saturating push along e pushes an amount of c(e) flow along the edge, thereby saturating the edge (and making it dissappear from the residual graph).
- A deactivating push along e = (u, v) pushes a flow of f(u), where f(u) is the excess flow of u. This makes u inactive.

162/242

```
Algorithm 1 maxflow(G, s, t, c)

1: find initial preflow f

2: while there is active node u do

3: if there is admiss. arc e out of u then

4: push(G, e, f, c)

5: else

6: relabel(u)

7: return f
```

```
Algorithm 1 maxflow(G, s, t, c)

1: find initial preflow f

2: while there is active node u do

3: if there is admiss. arc e out of u then

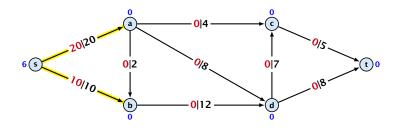

4: push(G, e, f, c)

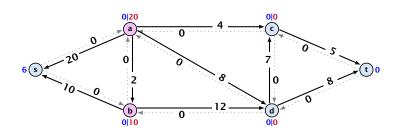

5: else

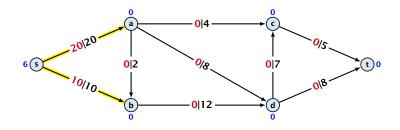

6: relabel(u)

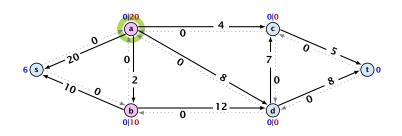

7: return f
```

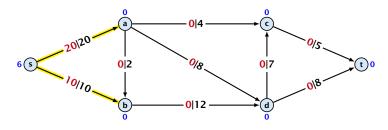

In the following example we always stick to the same active node \boldsymbol{u} until it becomes inactive but this is not required.

Lemma 30

An active node has a path to s in the residual graph.

Lemma 30

An active node has a path to s in the residual graph.

Proof.

Let A denote the set of nodes that can reach s, and let B denote the remaining nodes. Note that $s \in A$.

Lemma 30

An active node has a path to s in the residual graph.

Proof.

- Let A denote the set of nodes that can reach s, and let B denote the remaining nodes. Note that $s \in A$.
- In the following we show that a node $b \in B$ has excess flow f(b) = 0 which gives the lemma.

Lemma 30

An active node has a path to s in the residual graph.

Proof.

- Let A denote the set of nodes that can reach s, and let B denote the remaining nodes. Note that $s \in A$.
- In the following we show that a node $b \in B$ has excess flow f(b) = 0 which gives the lemma.
- ▶ In the residual graph there are no edges into A, and, hence, no edges leaving A/entering B can carry any flow.

Lemma 30

An active node has a path to s in the residual graph.

Proof.

- Let A denote the set of nodes that can reach s, and let B denote the remaining nodes. Note that $s \in A$.
- In the following we show that a node $b \in B$ has excess flow f(b) = 0 which gives the lemma.
- ► In the residual graph there are no edges into A, and, hence, no edges leaving A/entering B can carry any flow.
- Let $f(B) = \sum_{v \in B} f(v)$ be the excess flow of all nodes in B.

$$f(x,y) = \begin{cases} 0 & (x,y) \notin E \\ f((x,y)) & (x,y) \in E \end{cases}$$

$$f(x,y) = \begin{cases} 0 & (x,y) \notin E \\ f((x,y)) & (x,y) \in E \end{cases}$$

$$f(B) = \sum_{b \in B} f(b)$$

$$= \sum_{b \in B} \left(\sum_{v \in V} f(v, b) - \sum_{v \in V} f(b, v) \right)$$

$$= \sum_{b \in B} \left(\sum_{v \in A} f(v, b) + \sum_{v \in B} f(v, b) - \sum_{v \in A} f(b, v) - \sum_{v \in B} f(b, v) \right)$$

$$= -\sum_{b \in B} \sum_{v \in A} f(b, v)$$

$$f(x,y) = \begin{cases} 0 & (x,y) \notin E \\ f((x,y)) & (x,y) \in E \end{cases}$$

$$\begin{split} f(B) &= \sum_{b \in B} f(b) \\ &= \sum_{b \in B} \left(\sum_{v \in V} f(v, b) - \sum_{v \in V} f(b, v) \right) \\ &= \sum_{b \in B} \left(\sum_{v \in A} f(v, b) + \sum_{v \in B} f(v, b) - \sum_{v \in A} f(b, v) - \sum_{v \in B} f(b, v) \right) \\ &= - \sum_{b \in B} \sum_{v \in A} f(b, v) \end{split}$$

$$f(x,y) = \begin{cases} 0 & (x,y) \notin E \\ f((x,y)) & (x,y) \in E \end{cases}$$

$$\begin{split} f(B) &= \sum_{b \in B} f(b) \\ &= \sum_{b \in B} \left(\sum_{v \in V} f(v, b) - \sum_{v \in V} f(b, v) \right) \\ &= \sum_{b \in B} \left(\sum_{v \in A} f(v, b) + \sum_{v \in B} f(v, b) - \sum_{v \in A} f(b, v) - \sum_{v \in B} f(b, v) \right) \\ &= -\sum_{b \in B} \sum_{v \in A} f(b, v) \\ &\leq 0 \end{split}$$

$$f(x,y) = \begin{cases} 0 & (x,y) \notin E \\ f((x,y)) & (x,y) \in E \end{cases}$$

We have

$$\begin{split} f(B) &= \sum_{b \in B} f(b) \\ &= \sum_{b \in B} \left(\sum_{v \in V} f(v, b) - \sum_{v \in V} f(b, v) \right) \\ &= \sum_{b \in B} \left(\sum_{v \in A} f(v, b) + \sum_{v \in B} f(v, b) - \sum_{v \in A} f(b, v) - \sum_{v \in B} f(b, v) \right) \\ &= -\sum_{b \in B} \sum_{v \in A} f(b, v) \\ &\leq 0 \end{split}$$

Hence, the excess flow f(b) must be 0 for every node $b \in B$.

Lemma 31

The label of a node cannot become larger than 2n-1.

Lemma 31

The label of a node cannot become larger than 2n-1.

Proof.

When increasing the label at a node u there exists a path from u to s of length at most n-1. Along each edge of the path the height/label can at most drop by 1, and the label of the source is n.

Lemma 31

The label of a node cannot become larger than 2n-1.

Proof.

When increasing the label at a node u there exists a path from u to s of length at most n-1. Along each edge of the path the height/label can at most drop by 1, and the label of the source is n.

Lemma 32

There are only $O(n^2)$ relabel operations.

Lemma 33

The number of saturating pushes performed is at most O(mn).

Lemma 33

The number of saturating pushes performed is at most O(mn).

Proof.

Suppose that we just made a saturating push along (u, v).

Lemma 33

The number of saturating pushes performed is at most O(mn).

- Suppose that we just made a saturating push along (u, v).
- ▶ Hence, the edge (u, v) is deleted from the residual graph.

Lemma 33

The number of saturating pushes performed is at most O(mn).

- Suppose that we just made a saturating push along (u, v).
- ▶ Hence, the edge (u, v) is deleted from the residual graph.
- For the edge to appear again, a push from v to u is required.

Lemma 33

The number of saturating pushes performed is at most O(mn).

- Suppose that we just made a saturating push along (u, v).
- ▶ Hence, the edge (u, v) is deleted from the residual graph.
- For the edge to appear again, a push from v to u is required.
- Currently, $\ell(u) = \ell(v) + 1$, as we only make pushes along admissible edges.

Lemma 33

The number of saturating pushes performed is at most O(mn).

- Suppose that we just made a saturating push along (u, v).
- ▶ Hence, the edge (u, v) is deleted from the residual graph.
- For the edge to appear again, a push from v to u is required.
- Currently, $\ell(u) = \ell(v) + 1$, as we only make pushes along admissible edges.
- For a push from v to u the edge (v, u) must become admissible. The label of v must increase by at least 2.

Lemma 33

The number of saturating pushes performed is at most O(mn).

- Suppose that we just made a saturating push along (u, v).
- ▶ Hence, the edge (u, v) is deleted from the residual graph.
- For the edge to appear again, a push from v to u is required.
- Currently, $\ell(u) = \ell(v) + 1$, as we only make pushes along admissible edges.
- For a push from v to u the edge (v, u) must become admissible. The label of v must increase by at least 2.
- Since the label of v is at most 2n-1, there are at most n pushes along (u,v).

The number of deactivating pushes performed is at most $O(n^2m)$.

The number of deactivating pushes performed is at most $O(n^2m)$.

Proof.

▶ Define a potential function $\Phi(f) = \sum_{\text{active nodes } v} \ell(v)$

The number of deactivating pushes performed is at most $\mathcal{O}(n^2m)$.

- ▶ Define a potential function $\Phi(f) = \sum_{\text{active nodes } v} \ell(v)$
- A saturating push increases Φ by $\leq 2n$ (when the target node becomes active it may contribute at most 2n to the sum).

The number of deactivating pushes performed is at most $\mathcal{O}(n^2m)$.

- ▶ Define a potential function $\Phi(f) = \sum_{\text{active nodes } v} \ell(v)$
- A saturating push increases Φ by $\leq 2n$ (when the target node becomes active it may contribute at most 2n to the sum).
- ▶ A relabel increases Φ by at most 1.

The number of deactivating pushes performed is at most $\mathcal{O}(n^2m)$.

- ▶ Define a potential function $\Phi(f) = \sum_{\text{active nodes } v} \ell(v)$
- A saturating push increases Φ by $\leq 2n$ (when the target node becomes active it may contribute at most 2n to the sum).
- A relabel increases Φ by at most 1.
- A deactivating push decreases Φ by at least 1 as the node that is pushed from becomes inactive and has a label that is strictly larger than the target.

The number of deactivating pushes performed is at most $O(n^2m)$.

- ▶ Define a potential function $\Phi(f) = \sum_{\text{active nodes } v} \ell(v)$
- A saturating push increases Φ by $\leq 2n$ (when the target node becomes active it may contribute at most 2n to the sum).
- A relabel increases Φ by at most 1.
- A deactivating push decreases Φ by at least 1 as the node that is pushed from becomes inactive and has a label that is strictly larger than the target.
- Hence,

```
\#deactivating_pushes \leq \#relabels +2n \cdot \#saturating_pushes \leq \mathcal{O}(n^2m).
```

Theorem 35

There is an implementation of the generic push relabel algorithm with running time $\mathcal{O}(n^2m)$.

Proof:

Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

A push along an edge (u, v) can be performed in constant time

lacksquare check whether edge (v,u) needs to be added to G_f

Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

A push along an edge (u, v) can be performed in constant time

- lacksquare check whether edge (v,u) needs to be added to G_f
- check whether (u, v) needs to be deleted (saturating push)

Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

A push along an edge (u, v) can be performed in constant time

- lacksquare check whether edge (v,u) needs to be added to G_f
- check whether (u, v) needs to be deleted (saturating push)
- check whether u becomes inactive and has to be deleted from the set of active nodes

Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

A push along an edge (u, v) can be performed in constant time

- lacksquare check whether edge (v,u) needs to be added to G_f
- check whether (u, v) needs to be deleted (saturating push)
- check whether u becomes inactive and has to be deleted from the set of active nodes

A relabel at a node u can be performed in time O(n)

check for all outgoing edges if they become admissible

Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

A push along an edge (u, v) can be performed in constant time

- lacksquare check whether edge (v,u) needs to be added to G_f
- check whether (u, v) needs to be deleted (saturating push)
- check whether u becomes inactive and has to be deleted from the set of active nodes

A relabel at a node u can be performed in time O(n)

- check for all outgoing edges if they become admissible
- check for all incoming edges if they become non-admissible

For special variants of push relabel algorithms we organize the neighbours of a node into a linked list (possible neighbours in the residual graph G_f). Then we use the discharge-operation:

```
Algorithm 2 discharge(u)
1: while u is active do
        v \leftarrow u.current-neighbour
2:
      if v = \text{null then}
3:
             relabel(u)
4:
5:
             u.current-neighbour ← u.neighbour-list-head
        else
6:
7:
             if (u, v) admissible then push(u, v)
             else u.current-neighbour \leftarrow v.next-in-list
8:
```

Note that *u.current-neighbour* is a global variable. It is only changed within the discharge routine, but keeps its value between consecutive calls to discharge.

If v = null in Line 3, then there is no outgoing admissible edge from u.

Proof.

- While pushing from u the current-neighbour pointer is only advanced if the current edge is not admissible.
- The only thing that could make the edge admissible again would be a relabel at u.
- If we reach the end of the list (v = null) all edges are not admissible.

This shows that discharge(u) is correct, and that we can perform a relabel in Line 4.

13.2 Relabel to Front

```
Algorithm 1 relabel-to-front(G, s, t)
1: initialize preflow
2: initialize node list L containing V \setminus \{s, t\} in any order
3: foreach u \in V \setminus \{s, t\} do
         u.current-neighbour \leftarrow u.neighbour-list-head
4:
5: u \leftarrow L.head
6: while u \neq \text{null do}
         old-height \leftarrow \ell(u)
7:
         discharge(u)
8:
         if \ell(u) > old-height then // relabel happened
9:
10:
               move u to the front of L
11:
         u \leftarrow u.next
```

13.2 Relabel to Front

Lemma 37 (Invariant)

In Line 6 of the relabel-to-front algorithm the following invariant holds.

- 1. The sequence L is topologically sorted w.r.t. the set of admissible edges; this means for an admissible edge (x,y) the node x appears before y in sequence L.
- **2.** No node before u in the list L is active.

Proof:

- Initialization:
 - 1. In the beginning s has label $n \ge 2$, and all other nodes have label 0. Hence, no edge is admissible, which means that any ordering L is permitted.
 - 2. We start with u being the head of the list; hence no node before u can be active

Maintenance:

- Pushes do no create any new admissible edges. Therefore, if discharge() does not relabel u, L is still topologically sorted.
 - After relabeling, u cannot have admissible incoming edges as such an edge (x, u) would have had a difference $\ell(x) \ell(u) \ge 2$ before the re-labeling (such edges do not exist in the residual graph).

Hence, moving u to the front does not violate the sorting property for any edge; however it fixes this property for all admissible edges leaving u that were generated by the relabeling.

13.2 Relabel to Front

Proof:

- Maintenance:
 - 2. If we do a relabel there is nothing to prove because the only node before u' (u in the next iteration) will be the current u; the discharge(u) operation only terminates when u is not active anymore.

For the case that we do not relabel, observe that the only way a predecessor could be active is that we push flow to it via an admissible arc. However, all admissible arc point to successors of u.

Note that the invariant means that for u = null we have a preflow with a valid labelling that does not have active nodes. This means we have a maximum flow.

Lemma 38

There are at most $O(n^3)$ calls to discharge(u).

Every discharge operation without a relabel advances u (the current node within list L). Hence, if we have n discharge operations without a relabel we have u = null and the algorithm terminates.

Therefore, the number of calls to discharge is at most $n(\#relabels + 1) = O(n^3)$.

Lemma 39

The cost for all relabel-operations is only $\mathcal{O}(n^2)$.

A relabel-operation at a node is constant time (increasing the label and resetting *u.current-neighbour*). In total we have $\mathcal{O}(n^2)$ relabel-operations.

Recall that a saturating push operation $(\min\{c_f(e), f(u)\} = c_f(e))$ can also be a deactivating push operation $(\min\{c_f(e), f(u)\} = f(u))$.

Lemma 40

The cost for all saturating push-operations that are **not** deactivating is only O(mn).

Note that such a push-operation leaves the node u active but makes the edge e disappear from the residual graph. Therefore the push-operation is immediately followed by an increase of the pointer u.current-neighbour.

This pointer can traverse the neighbour-list at most $\mathcal{O}(n)$ times (upper bound on number of relabels) and the neighbour-list has only degree(u) + 1 many entries (+1 for null-entry).

Lemma 41

The cost for all deactivating push-operations is only $O(n^3)$.

A deactivating push-operation takes constant time and ends the current call to discharge(). Hence, there are only $\mathcal{O}(n^3)$ such operations.

Theorem 42

The push-relabel algorithm with the rule relabel-to-front takes time $\mathcal{O}(n^3)$.

Algorithm 1 highest-label (G, s, t)

- 1: initialize preflow
- 2: **foreach** $u \in V \setminus \{s, t\}$ **do**
- 3: $u.current-neighbour \leftarrow u.neighbour-list-head$
- 4: **while** \exists active node u **do**
- 5: select active node u with highest label
- 6: $\operatorname{discharge}(u)$

Lemma 43

When using highest label the number of deactivating pushes is only $\mathcal{O}(n^3)$.

A push from a node on level ℓ can only "activate" nodes on levels strictly less than ℓ .

This means, after a deactivating push from \boldsymbol{u} a relabel is required to make \boldsymbol{u} active again.

Hence, after n deactivating pushes without an intermediate relabel there are no active nodes left.

Therefore, the number of deactivating pushes is at most $n(\#relabels + 1) = \mathcal{O}(n^3)$.

Since a discharge-operation is terminated by a deactivating push this gives an upper bound of $\mathcal{O}(n^3)$ on the number of discharge-operations.

The cost for relabels and saturating pushes can be estimated in exactly the same way as in the case of the generic push-relabel algorithm.

Question:

How do we find the next node for a discharge operation?

Maintain lists L_i , $i \in \{0, ..., 2n\}$, where list L_i contains active nodes with label i (maintaining these lists induces only constant additional cost for every push-operation and for every relabel-operation).

After a discharge operation terminated for a node u with label k, traverse the lists $L_k, L_{k-1}, \ldots, L_0$, (in that order) until you find a non-empty list.

Unless the last (deactivating) push was to s or t the list k-1 must be non-empty (i.e., the search takes constant time).

Hence, the total time required for searching for active nodes is at most

$$O(n^3) + n(\# deactivating-pushes-to-s-or-t)$$

Lemma 44

The number of deactivating pushes to s or t is at most $\mathcal{O}(n^2)$.

With this lemma we get

Theorem 45

The push-relabel algorithm with the rule highest-label takes time $\mathcal{O}(n^3)$.

Proof of the Lemma.

- We only show that the number of pushes to the source is at most $\mathcal{O}(n^2)$. A similar argument holds for the target.
- After a node v (which must have $\ell(v) = n+1$) made a deactivating push to the source there needs to be another node whose label is increased from $\leq n+1$ to n+2 before v can become active again.
- This happens for every push that v makes to the source. Since, every node can pass the threshold n+2 at most once, v can make at most n pushes to the source.
- As this holds for every node the total number of pushes to the source is at most $\mathcal{O}(n^2)$.

$$\begin{aligned} & \min & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E : & 0 \leq f(e) \leq u(e) \\ & & \forall v \in V : & f(v) = b(v) \end{aligned}$$

Problem Definition:

$$\begin{array}{ll} \min & \sum_{e} c(e) f(e) \\ \text{s.t.} & \forall e \in E \colon \ 0 \leq f(e) \leq u(e) \\ & \forall v \in V \colon \ f(v) = b(v) \end{array}$$

We can assume that a(v) = b(v):

Add new node r.

Add edge (r, v) for all $v \in V$.

Set $\ell(e) = c(e) = 0$ for these edges.

$$\begin{aligned} & \min & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E: & \ell(e) \leq f(e) \leq u(e) \\ & & & \forall v \in V: & a(v) \leq f(v) \leq b(v) \end{aligned}$$

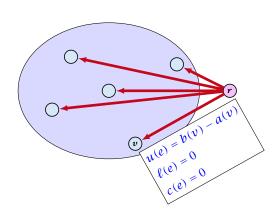

We can assume that a(v) = b(v):

Add new node r.

Add edge (r, v) for all $v \in V$.

Set $\ell(e) = c(e) = 0$ for these edges.

Set u(e) = b(v) - a(v) for edge (r, v).

$$\begin{aligned} & \min & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E: & \ell(e) \leq f(e) \leq u(e) \\ & & & \forall v \in V: & a(v) \leq f(v) \leq b(v) \end{aligned}$$

We can assume that a(v) = b(v):

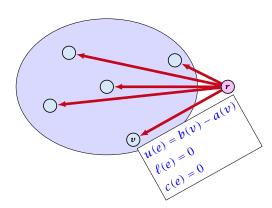

Add new node r.

Add edge (r, v) for all $v \in V$.

Set $\ell(e) = c(e) = 0$ for these edges.

Set u(e) = b(v) - a(v) for edge (r, v).

Set a(v) = b(v) for all $v \in V$.

$$\begin{aligned} & \min & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E: & \ell(e) \leq f(e) \leq u(e) \\ & & & \forall v \in V: & a(v) \leq f(v) \leq b(v) \end{aligned}$$

We can assume that a(v) = b(v):

Add new node r.

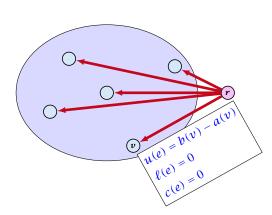

Add edge (r, v) for all $v \in V$.

Set $\ell(e) = c(e) = 0$ for these edges.

Set u(e) = b(v) - a(v) for edge (r, v).

Set a(v) = b(v) for all $v \in V$.

Set $b(r) = -\sum_{v \in V} b(v)$.

$$\begin{aligned} & \min \quad \sum_{e} c(e) f(e) \\ & \text{s.t.} \quad \forall e \in E: \ \ell(e) \leq f(e) \leq u(e) \\ & \quad \forall v \in V: \ a(v) \leq f(v) \leq b(v) \end{aligned}$$

We can assume that a(v) = b(v):

Add new node r.

Add edge (r, v) for all $v \in V$.

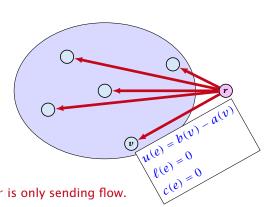

Set $\ell(e) = c(e) = 0$ for these edges.

Set u(e) = b(v) - a(v) for edge (r, v).

Set a(v) = b(v) for all $v \in V$.

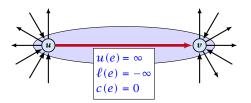

Set
$$b(r) = -\sum_{v \in V} b(v)$$
.

 $-\sum_{v}b(v)$ is negative; hence r is only sending flow.

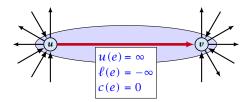

$$\begin{aligned} & \min & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E : & \ell(e) \leq f(e) \leq u(e) \\ & & \forall v \in V : & f(v) = b(v) \end{aligned}$$

We can assume that either $\ell(e) \neq -\infty$ or $u(e) \neq \infty$:

$$\begin{aligned} & \text{min} & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E : & \ell(e) \leq f(e) \leq u(e) \\ & & \forall v \in V : & f(v) = b(v) \end{aligned}$$

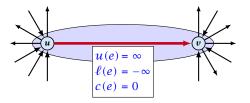

We can assume that either $\ell(e) \neq -\infty$ or $u(e) \neq \infty$:

If c(e) = 0 we can contract the edge/identify nodes u and v.

$$\begin{aligned} & \text{min} & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E: & \ell(e) \leq f(e) \leq u(e) \\ & & \forall v \in V: & f(v) = b(v) \end{aligned}$$

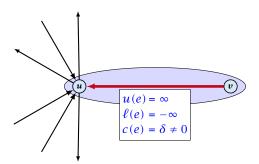

We can assume that either $\ell(e) \neq -\infty$ or $u(e) \neq \infty$:

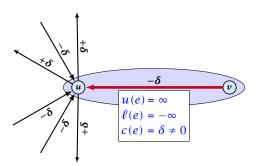

If c(e) = 0 we can contract the edge/identify nodes u and v.

If $c(e) \neq 0$ we can transform the graph so that c(e) = 0.

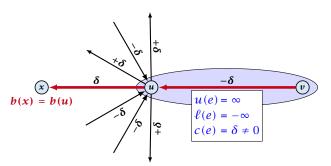

We can transform any network so that a particular edge has cost c(e) = 0:

We can transform any network so that a particular edge has cost c(e) = 0:

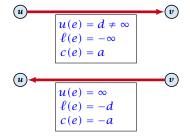

We can transform any network so that a particular edge has cost c(e) = 0:

Additionally we set b(u) = 0.

$$\begin{aligned} & \min & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E : & \ell(e) \leq f(e) \leq u(e) \\ & & \forall v \in V : & f(v) = b(v) \end{aligned}$$

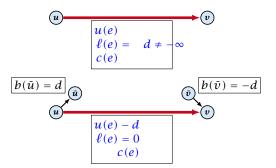

We can assume that $\ell(e) \neq -\infty$:

Replace the edge by an edge in opposite direction.

$$\begin{aligned} & \min & & \sum_{e} c(e) f(e) \\ & \text{s.t.} & & \forall e \in E : & \ell(e) \leq f(e) \leq u(e) \\ & & \forall v \in V : & f(v) = b(v) \end{aligned}$$

We can assume that $\ell(e) = 0$:

The added edges have infinite capacity and cost c(e)/2.

Caterer Problem

▶ She needs to supply r_i napkins on N successive days.

cost: c(e) = 0

Residual Graph

Version A:

The residual graph G' for a mincost flow is just a copy of the graph G.

If we send f(e) along an edge, the corresponding edge e' in the residual graph has its lower and upper bound changed to $\ell(e') = \ell(e) - f(e)$ and u(e') = u(e) - f(e).

Residual Graph

Version A:

The residual graph G' for a mincost flow is just a copy of the graph G.

If we send f(e) along an edge, the corresponding edge e' in the residual graph has its lower and upper bound changed to $\ell(e') = \ell(e) - f(e)$ and u(e') = u(e) - f(e).

Version B:

The residual graph for a mincost flow is exactly defined as the residual graph for standard flows, with the only exception that one needs to define a cost for the residual edge.

For a flow of z from u to v the residual edge (v,u) has capacity z and a cost of -c((u,v)).

200/242

A circulation in a graph G=(V,E) is a function $f:E\to\mathbb{R}^+$ that has an excess flow f(v)=0 for every node $v\in V$.

A circulation in a graph G=(V,E) is a function $f:E\to\mathbb{R}^+$ that has an excess flow f(v)=0 for every node $v\in V$.

A circulation is feasible if it fulfills capacity constraints, i.e., $f(e) \le u(e)$ for every edge of G.

A given flow is a mincost-flow if and only if the corresponding residual graph G_f does not have a feasible circulation of negative cost.

A given flow is a mincost-flow if and only if the corresponding residual graph G_f does not have a feasible circulation of negative cost.

 \Rightarrow Suppose that g is a feasible circulation of negative cost in the residual graph.

A given flow is a mincost-flow if and only if the corresponding residual graph G_f does not have a feasible circulation of negative cost.

 \Rightarrow Suppose that g is a feasible circulation of negative cost in the residual graph.

Then f+g is a feasible flow with cost $\cos t(f)+\cos t(g)<\cos t(f)$. Hence, f is not minimum cost.

A given flow is a mincost-flow if and only if the corresponding residual graph G_f does not have a feasible circulation of negative cost.

 \Rightarrow Suppose that g is a feasible circulation of negative cost in the residual graph.

Then f + g is a feasible flow with cost cost(f) + cost(g) < cost(f). Hence, f is not minimum cost.

 \Leftarrow Let f be a non-mincost flow, and let f^* be a min-cost flow. We need to show that the residual graph has a feasible circulation with negative cost.

A given flow is a mincost-flow if and only if the corresponding residual graph G_f does not have a feasible circulation of negative cost.

 \Rightarrow Suppose that g is a feasible circulation of negative cost in the residual graph.

Then f+g is a feasible flow with cost $\cos(f)+\cos(g)<\cos(f)$. Hence, f is not minimum cost.

 \leftarrow Let f be a non-mincost flow, and let f^* be a min-cost flow. We need to show that the residual graph has a feasible circulation with negative cost.

Clearly $f^* - f$ is a circulation of negative cost. One can also easily see that it is feasible for the residual graph. (after sending -f in the residual graph (pushing all flow back) we arrive at the original graph; for this f^* is clearly feasible)

Lemma 47

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights $c: E \to \mathbb{R}$.

Lemma 47

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights $c : E \to \mathbb{R}$.

Proof.

Suppose that we have a negative cost circulation.

Lemma 47

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights $c : E \to \mathbb{R}$.

Proof.

- Suppose that we have a negative cost circulation.
- Find directed cycle only using edges that have non-zero flow.

204/242

Lemma 47

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights $c : E \to \mathbb{R}$.

Proof.

- Suppose that we have a negative cost circulation.
- Find directed cycle only using edges that have non-zero flow.
- If this cycle has negative cost you are done.

Lemma 47

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights $c : E \to \mathbb{R}$.

Proof.

- Suppose that we have a negative cost circulation.
- Find directed cycle only using edges that have non-zero flow.
- If this cycle has negative cost you are done.
- Otherwise send flow in opposite direction along the cycle until the bottleneck edge(s) does not carry any flow.

204/242

Lemma 47

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights $c : E \to \mathbb{R}$.

Proof.

- Suppose that we have a negative cost circulation.
- Find directed cycle only using edges that have non-zero flow.
- If this cycle has negative cost you are done.
- Otherwise send flow in opposite direction along the cycle until the bottleneck edge(s) does not carry any flow.
- You still have a circulation with negative cost.

Lemma 47

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights $c: E \to \mathbb{R}$.

Proof.

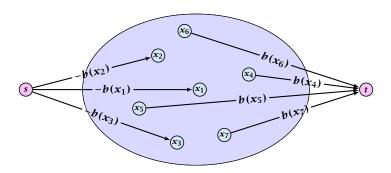

- Suppose that we have a negative cost circulation.
- Find directed cycle only using edges that have non-zero flow.
- If this cycle has negative cost you are done.
- Otherwise send flow in opposite direction along the cycle until the bottleneck edge(s) does not carry any flow.
- You still have a circulation with negative cost.
- Repeat.

Algorithm 23 CycleCanceling(G = (V, E), c, u, b)

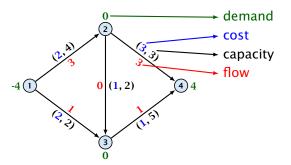

- 1: establish a feasible flow f in G
- 2: **while** G_f contains negative cycle **do**
- 3: use Bellman-Ford to find a negative circuit Z
- 4: $\delta \leftarrow \min\{u_f(e) \mid e \in Z\}$
- 5: augment δ units along Z and update G_f

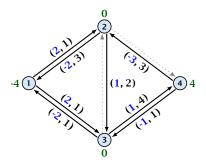

How do we find the initial feasible flow?

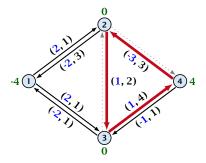

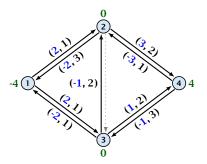

- Connect new node s to all nodes with negative b(v)-value.
- Connect nodes with positive b(v)-value to a new node t.
- ► There exist a feasible flow in the original graph iff in the resulting graph there exists an *s-t* flow of value

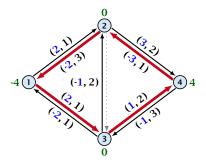

$$\sum_{v:b(v)<0} (-b(v)) = \sum_{v:b(v)>0} b(v) .$$

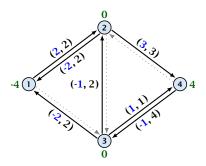

Lemma 48

The improving cycle algorithm runs in time $O(nm^2CU)$, for integer capacities and costs, when for all edges e, $|c(e)| \le C$ and $|u(e)| \le U$.

- Running time of Bellman-Ford is O(mn).
- Pushing flow along the cycle can be done in time O(n).
- Each iteration decreases the total cost by at least 1.
- ▶ The true optimum cost must lie in the interval [-mCU,...,+mCU].

Note that this lemma is weak since it does not allow for edges with infinite capacity.

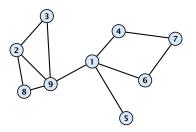

209/242

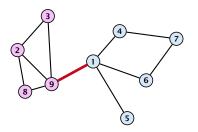

A general mincost flow problem is of the following form:

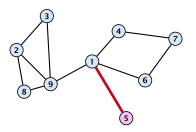

$$\begin{aligned} & \min \quad \sum_{e} c(e) f(e) \\ & \text{s.t.} \quad \forall e \in E : \quad \ell(e) \leq f(e) \leq u(e) \\ & \quad \forall v \in V : \quad a(v) \leq f(v) \leq b(v) \end{aligned}$$
 where $a: V \to \mathbb{R}, \ b: V \to \mathbb{R}; \ \ell: E \to \mathbb{R} \cup \{-\infty\}, \ u: E \to \mathbb{R} \cup \{\infty\}$ $c: E \to \mathbb{R}$:

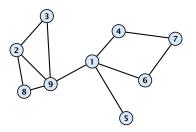

Lemma 49 (without proof)

A general mincost flow problem can be solved in polynomial time.

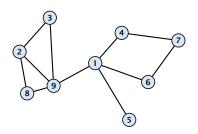

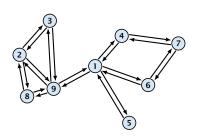

We can solve this problem using standard maxflow/mincut.

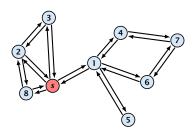

We can solve this problem using standard maxflow/mincut.

Construct a directed graph G' = (V, E') that has edges (u, v) and (v, u) for every edge $\{u, v\} \in E$.

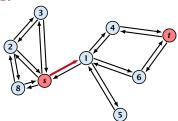

We can solve this problem using standard maxflow/mincut.

- Construct a directed graph G' = (V, E') that has edges (u, v) and (v, u) for every edge $\{u, v\} \in E$.
- Fix an arbitrary node $s \in V$ as source. Compute a minimum s-t cut for all possible choices $t \in V$, $t \neq s$. (Time: $\mathcal{O}(n^4)$)

We can solve this problem using standard maxflow/mincut.

- Construct a directed graph G' = (V, E') that has edges (u, v) and (v, u) for every edge $\{u, v\} \in E$.
- Fix an arbitrary node $s \in V$ as source. Compute a minimum s-t cut for all possible choices $t \in V$, $t \neq s$. (Time: $\mathcal{O}(n^4)$)
- Let $(S, V \setminus S)$ be a minimum global mincut. The above algorithm will output a cut of capacity $cap(S, V \setminus S)$ whenever $|\{s,t\} \cap S| = 1$.

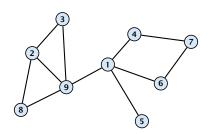

• Given a graph G = (V, E) and an edge $e = \{u, v\}$.

- Given a graph G = (V, E) and an edge $e = \{u, v\}$.
- ▶ The graph G/e is obtained by "identifying" u and v to form a new node.

- Given a graph G = (V, E) and an edge $e = \{u, v\}$.
- The graph G/e is obtained by "identifying" u and v to form a new node.
- Resulting parallel edges are replaced by a single edge, whose capacity equals the sum of capacities of the parallel edges.

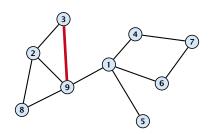

- Given a graph G = (V, E) and an edge $e = \{u, v\}$.
- ▶ The graph G/e is obtained by "identifying" u and v to form a new node.
- Resulting parallel edges are replaced by a single edge, whose capacity equals the sum of capacities of the parallel edges.

Example 50

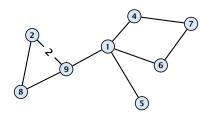

- Given a graph G = (V, E) and an edge $e = \{u, v\}$.
- ▶ The graph G/e is obtained by "identifying" u and v to form a new node.
- Resulting parallel edges are replaced by a single edge, whose capacity equals the sum of capacities of the parallel edges.

Example 50

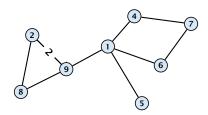

- Given a graph G = (V, E) and an edge $e = \{u, v\}$.
- The graph G/e is obtained by "identifying" u and v to form a new node.
- Resulting parallel edges are replaced by a single edge, whose capacity equals the sum of capacities of the parallel edges.

Example 50

- Given a graph G = (V, E) and an edge $e = \{u, v\}$.
- The graph G/e is obtained by "identifying" u and v to form a new node.
- Resulting parallel edges are replaced by a single edge, whose capacity equals the sum of capacities of the parallel edges.

Example 50

Edge-contractions do no decrease the size of the mincut.

We can perform an edge-contraction in time O(n).

- 1: **for** $i = 1 \rightarrow n 2$ **do**
- 2: choose $e \in E$ randomly with probability c(e)/c(E)
- 3: $G \leftarrow G/e$
- 4: **return** only cut in G

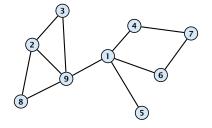

- 1: **for** $i = 1 \rightarrow n 2$ **do**
- 2: choose $e \in E$ randomly with probability c(e)/c(E)
- 3: $G \leftarrow G/e$
- 4: **return** only cut in *G*
- Let G_t denote the graph after the (n-t)-th iteration, when t nodes are left.

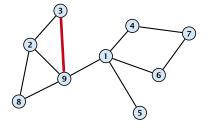

- 1: **for** $i = 1 \rightarrow n 2$ **do**
- 2: choose $e \in E$ randomly with probability c(e)/c(E)
- 3: $G \leftarrow G/e$
- 4: return only cut in G
- Let G_t denote the graph after the (n-t)-th iteration, when t nodes are left.
- Note that the final graph G_2 only contains a single edge.

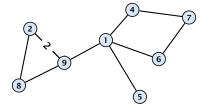

- 1: **for** $i = 1 \rightarrow n 2$ **do**
- 2: choose $e \in E$ randomly with probability c(e)/c(E)
- 3: $G \leftarrow G/e$
- 4: **return** only cut in *G*
- Let G_t denote the graph after the (n-t)-th iteration, when t nodes are left.
- Note that the final graph G_2 only contains a single edge.
- ► The cut in *G*₂ corresponds to a cut in the original graph *G* with the same capacity.

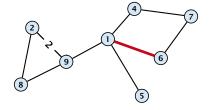

- 1: **for** $i = 1 \rightarrow n 2$ **do**
- 2: choose $e \in E$ randomly with probability c(e)/c(E)
- 3: $G \leftarrow G/e$
- 4: return only cut in G
- Let G_t denote the graph after the (n-t)-th iteration, when t nodes are left.
- Note that the final graph G_2 only contains a single edge.
- ► The cut in *G*² corresponds to a cut in the original graph *G* with the same capacity.
- What is the probability that this algorithm returns a mincut?

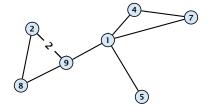

Example: Randomized Mincut Algorithm

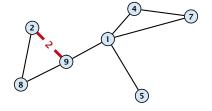

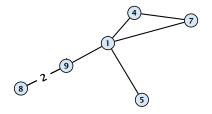

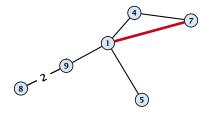

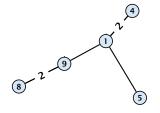

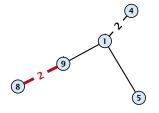

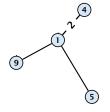

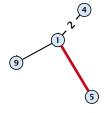

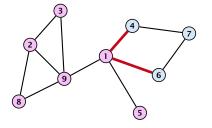

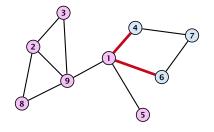

What is the probability that this algorithm returns a mincut?

What is the probability that a given mincut A is still possible after round i?

▶ It is still possible to obtain cut A in the end if so far no edge in $(A, V \setminus A)$ has been contracted.

What is the probability that we select an edge from A in iteration i?

Let $min = cap(A, V \setminus A)$ denote the capacity of a mincut.

- Let $min = cap(A, V \setminus A)$ denote the capacity of a mincut.
- Let cap(v) be capacity of edges incident to vertex $v \in V_{n-i+1}$.

- Let $min = cap(A, V \setminus A)$ denote the capacity of a mincut.
- Let cap(v) be capacity of edges incident to vertex $v \in V_{n-i+1}$.
- ► Clearly, $cap(v) \ge min$.

- Let $\min = \operatorname{cap}(A, V \setminus A)$ denote the capacity of a mincut.
- Let cap(v) be capacity of edges incident to vertex $v \in V_{n-i+1}$.
- ▶ Clearly, $cap(v) \ge min$.
- Summing cap(v) over all edges gives

$$2c(E) = 2\sum_{e \in E} c(e) = \sum_{v \in V} \operatorname{cap}(v) \ge (n - i + 1) \cdot \min$$

What is the probability that we select an edge from A in iteration i?

- Let $\min = \operatorname{cap}(A, V \setminus A)$ denote the capacity of a mincut.
- Let cap(v) be capacity of edges incident to vertex $v \in V_{n-i+1}$.
- ▶ Clearly, $cap(v) \ge min$.
- Summing cap(v) over all edges gives

$$2c(E) = 2\sum_{e \in E} c(e) = \sum_{v \in V} cap(v) \ge (n - i + 1) \cdot min$$

► Hence, the probability of choosing an edge from the cut is at most $\min / c(E) \le 2/(n-i+1)$.

218/242

The probability that we do not choose an edge from the cut in iteration i is

$$1 - \frac{2}{n-i+1} = \frac{n-i-1}{n-i+1} .$$

The probability that we do not choose an edge from the cut in iteration i is

$$1 - \frac{2}{n-i+1} = \frac{n-i-1}{n-i+1} \ .$$

The probability that the cut is alive after iteration n-t (after which t nodes are left) is at most

$$\prod_{i=1}^{n-t} \frac{n-i-1}{n-i+1} = \frac{t(t-1)}{n(n-1)}.$$

The probability that we do not choose an edge from the cut in iteration i is

$$1 - \frac{2}{n-i+1} = \frac{n-i-1}{n-i+1} \ .$$

The probability that the cut is alive after iteration n-t (after which t nodes are left) is at most

$$\prod_{i=1}^{n-t} \frac{n-i-1}{n-i+1} = \frac{t(t-1)}{n(n-1)} .$$

Choosing t=2 gives that with probability $1/\binom{n}{2}$ the algorithm computes a mincut.

Repeating the algorithm $c \ln n \binom{n}{2}$ times

Repeating the algorithm $c \ln n \binom{n}{2}$ times gives that the probability that we are never successful is

$$\left(1 - \frac{1}{\binom{n}{2}}\right)^{\binom{n}{2}c\ln n}$$

Repeating the algorithm $c \ln n \binom{n}{2}$ times gives that the probability that we are never successful is

$$\left(1 - \frac{1}{\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le \left(e^{-1/\binom{n}{2}}\right)^{\binom{n}{2}c\ln n}$$

Repeating the algorithm $c \ln n \binom{n}{2}$ times gives that the probability that we are never successful is

$$\left(1 - \frac{1}{\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le \left(e^{-1/\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le n^{-c} ,$$

Repeating the algorithm $c \ln n \binom{n}{2}$ times gives that the probability that we are never successful is

$$\left(1 - \frac{1}{\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le \left(e^{-1/\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le n^{-c} ,$$

where we used $1 - x \le e^{-x}$.

Repeating the algorithm $c \ln n \binom{n}{2}$ times gives that the probability that we are never successful is

$$\left(1 - \frac{1}{\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le \left(e^{-1/\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le n^{-c} ,$$

where we used $1 - x \le e^{-x}$.

Theorem 51

The randomized mincut algorithm computes an optimal cut with high probability. The total running time is $O(n^4 \log n)$.

Improved Algorithm

```
Algorithm 2 RecursiveMincut(G = (V, E, c))

1: for i = 1 \rightarrow n - n/\sqrt{2} do

2: choose e \in E randomly with probability c(e)/c(E)

3: G \leftarrow G/e

4: if |V| = 2 return cut-value;

5: cuta \leftarrow \text{RecursiveMincut}(G);

6: cutb \leftarrow \text{RecursiveMincut}(G);

7: return \min\{cuta, cutb\}
```

Improved Algorithm

```
Algorithm 2 RecursiveMincut(G = (V, E, c))

1: for i = 1 \rightarrow n - n/\sqrt{2} do

2: choose e \in E randomly with probability c(e)/c(E)

3: G \leftarrow G/e

4: if |V| = 2 return cut-value;

5: cuta \leftarrow \text{RecursiveMincut}(G);

6: cutb \leftarrow \text{RecursiveMincut}(G);
```

Running time:

$$T(n) = 2T\left(\frac{n}{\sqrt{2}}\right) + \mathcal{O}(n^2)$$

7: **return** min{*cuta*, *cutb*}

Improved Algorithm

Algorithm 2 RecursiveMincut(G = (V, E, c))

- 1: **for** $i = 1 \to n n/\sqrt{2}$ **do**
- 2: choose $e \in E$ randomly with probability c(e)/c(E)
- 3: $G \leftarrow G/e$
- 4: **if** |V| = 2 **return** cut-value;
- 5: *cuta* ← RecursiveMincut(G);
- 6: *cutb* ← RecursiveMincut(G);
- 7: **return** min{*cuta*, *cutb*}

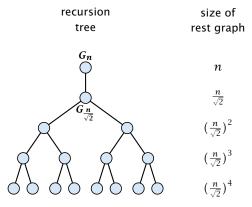

Running time:

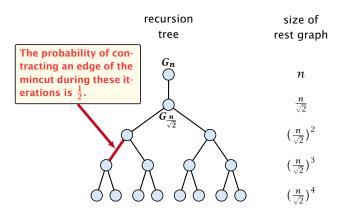

- $T(n) = 2T\left(\frac{n}{\sqrt{2}}\right) + \mathcal{O}(n^2)$
- ▶ This gives $T(n) = \mathcal{O}(n^2 \log n)$.

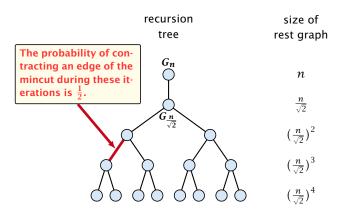

The probability of not contracting an edge from the mincut during one iteration through the for-loop is at least

$$\frac{t(t-1)}{n(n-1)} \ge \frac{t^2}{n^2} = \frac{1}{2} ,$$

as
$$t = \frac{n}{\sqrt{2}}$$
.

We can estimate the success probability by using the following game on the recursion tree. Delete every edge with probability $\frac{1}{2}$. If in the end you have a path from the root to at least one leaf node you are successful.

15 Global Mincut 19. Oct. 20

Let for an edge e in the recursion tree, h(e) denote the height (distance to leaf level) of the parent-node of e (end-point that is higher up in the tree). Let h denote the height of the root node.

Let for an edge e in the recursion tree, h(e) denote the height (distance to leaf level) of the parent-node of e (end-point that is higher up in the tree). Let h denote the height of the root node.

Call an edge *e* alive if there exists a path from the parent-node of *e* to a descendant leaf, after we randomly deleted edges. Note that an edge can only be alive if it hasn't been deleted.

Let for an edge e in the recursion tree, h(e) denote the height (distance to leaf level) of the parent-node of e (end-point that is higher up in the tree). Let h denote the height of the root node.

Call an edge *e* alive if there exists a path from the parent-node of *e* to a descendant leaf, after we randomly deleted edges. Note that an edge can only be alive if it hasn't been deleted.

Lemma 52

The probability that an edge e is alive is at least $\frac{1}{h(e)+1}$.

224/242

Proof.

An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.

- An edge e with h(e)=1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.

- An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.
- This happens with probability

Proof.

- An edge e with h(e)=1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.
- This happens with probability

 p_d

- An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.
- This happens with probability

$$p_d = \frac{1}{2} \left(2 p_{d-1} - p_{d-1}^2 \right)$$

- An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.
- This happens with probability

$$p_d = \frac{1}{2} (2p_{d-1} - p_{d-1}^2) \left[\Pr[A \vee B] = \Pr[A] + \Pr[B] - \Pr[A \wedge B] \right]$$

- An edge e with h(e)=1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.
- This happens with probability

$$p_{d} = \frac{1}{2} \left(2p_{d-1} - p_{d-1}^{2} \right) \left[\Pr[A \vee B] = \Pr[A] + \Pr[B] - \Pr[A \wedge B] \right]$$

$$= p_{d-1} - \frac{p_{d-1}^{2}}{2}$$

Proof.

- An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.
- This happens with probability

$$\begin{split} p_{d} &= \frac{1}{2} \Big(2 p_{d-1} - p_{d-1}^2 \Big) \ \ \boxed{\Pr[A \vee B] = \Pr[A] + \Pr[B] - \Pr[A \wedge B]} \\ &= p_{d-1} - \frac{p_{d-1}^2}{2} \end{split}$$

 $x - x^2/2$ is monotonically increasing for $x \in [0, 1]$

- An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.
- This happens with probability

$$p_d = \frac{1}{2} \Big(2 p_{d-1} - p_{d-1}^2 \Big) \quad \boxed{\Pr[A \vee B] = \Pr[A] + \Pr[B] - \Pr[A \wedge B]}$$

$$= p_{d-1} - \frac{p_{d-1}^2}{2}$$

$$x - x^2/2 \text{ is monotonically} \qquad 1 \qquad 1$$

$$|x-x^2/2|$$
 is monotonically increasing for $x \in [0,1]$ $\geq \frac{1}{d} - \frac{1}{2d^2}$

- An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least $\frac{1}{2}$.
- Let p_d be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge $e = \{c, p\}$ if it is not deleted **and** if one of the child-edges connecting to c is alive.

15 Global Mincut

Lemma 53

One run of the algorithm can be performed in time $O(n^2 \log n)$ and has a success probability of $O(\frac{1}{\log n})$.

15 Global Mincut

Lemma 53

One run of the algorithm can be performed in time $\mathcal{O}(n^2 \log n)$ and has a success probability of $\Omega(\frac{1}{\log n})$.

Doing $\Theta(\log^2 n)$ runs gives that the algorithm succeeds with high probability. The total running time is $\mathcal{O}(n^2 \log^3 n)$.

16 Gomory Hu Trees

Given an undirected, weighted graph G = (V, E, c) a cut-tree T = (V, F, w) is a tree with edge-set F and capacities w that fulfills the following properties.

- **1. Equivalent Flow Tree:** For any pair of vertices $s, t \in V$, f(s,t) in G is equal to $f_T(s,t)$.
- 2. Cut Property: A minimum s-t cut in T is also a minimum cut in G.

Here, f(s,t) is the value of a maximum s-t flow in G, and $f_T(s,t)$ is the corresponding value in T.

227/242

The algorithm maintains a partition of V, (sets S_1, \ldots, S_t), and a spanning tree T on the vertex set $\{S_1, \ldots, S_t\}$.

The algorithm maintains a partition of V, (sets S_1, \ldots, S_t), and a spanning tree T on the vertex set $\{S_1, \ldots, S_t\}$.

Initially, there exists only the set $S_1 = V$.

The algorithm maintains a partition of V, (sets S_1, \ldots, S_t), and a spanning tree T on the vertex set $\{S_1, \ldots, S_t\}$.

Initially, there exists only the set $S_1 = V$.

Then the algorithm performs n-1 split-operations:

The algorithm maintains a partition of V, (sets S_1, \ldots, S_t), and a spanning tree T on the vertex set $\{S_1, \ldots, S_t\}$.

Initially, there exists only the set $S_1 = V$.

Then the algorithm performs n-1 split-operations:

▶ In each such split-operation it chooses a set S_i with $|S_i| \ge 2$ and splits this set into two non-empty parts X and Y.

The algorithm maintains a partition of V, (sets S_1, \ldots, S_t), and a spanning tree T on the vertex set $\{S_1, \ldots, S_t\}$.

Initially, there exists only the set $S_1 = V$.

Then the algorithm performs n-1 split-operations:

- In each such split-operation it chooses a set S_i with $|S_i| \ge 2$ and splits this set into two non-empty parts X and Y.
- ▶ S_i is then removed from T and replaced by X and Y.

The algorithm maintains a partition of V, (sets S_1, \ldots, S_t), and a spanning tree T on the vertex set $\{S_1, \ldots, S_t\}$.

Initially, there exists only the set $S_1 = V$.

Then the algorithm performs n-1 split-operations:

- In each such split-operation it chooses a set S_i with $|S_i| \ge 2$ and splits this set into two non-empty parts X and Y.
- $ightharpoonup S_i$ is then removed from T and replaced by X and Y.
- X and Y are connected by an edge, and the edges that before the split were incident to S_i are attached to either X or Y.

The algorithm maintains a partition of V, (sets S_1, \ldots, S_t), and a spanning tree T on the vertex set $\{S_1, \ldots, S_t\}$.

Initially, there exists only the set $S_1 = V$.

Then the algorithm performs n-1 split-operations:

- In each such split-operation it chooses a set S_i with $|S_i| \ge 2$ and splits this set into two non-empty parts X and Y.
- ▶ S_i is then removed from T and replaced by X and Y.
- ➤ *X* and *Y* are connected by an edge, and the edges that before the split were incident to *S*_i are attached to either *X* or *Y*.

In the end this gives a tree on the vertex set V.

 \triangleright Select S_i that contains at least two nodes a and b.

- Select S_i that contains at least two nodes a and b.
- Compute the connected components of the forest obtained from the current tree T after deleting S_i . Each of these components corresponds to a set of vertices from V.

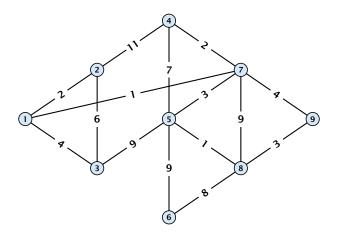

- Select S_i that contains at least two nodes a and b.
- Compute the connected components of the forest obtained from the current tree T after deleting S_i . Each of these components corresponds to a set of vertices from V.
- Consider the graph H obtained from G by contracting these connected components into single nodes.

- Select S_i that contains at least two nodes a and b.
- Compute the connected components of the forest obtained from the current tree T after deleting S_i . Each of these components corresponds to a set of vertices from V.
- Consider the graph H obtained from G by contracting these connected components into single nodes.
- Compute a minimum a-b cut in H. Let A, and B denote the two sides of this cut.

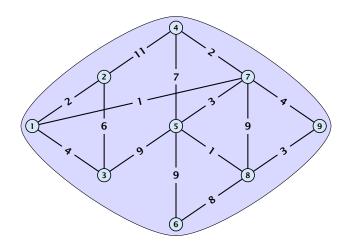

- Select S_i that contains at least two nodes a and b.
- Compute the connected components of the forest obtained from the current tree T after deleting S_i . Each of these components corresponds to a set of vertices from V.
- Consider the graph H obtained from G by contracting these connected components into single nodes.
- Compute a minimum a-b cut in H. Let A, and B denote the two sides of this cut.
- ▶ Split S_i in T into two sets/nodes $S_i^a = S_i \cap A$ and $S_i^b = S_i \cap B$ and add edge $\{S_i^a, S_i^b\}$ with capacity $f_H(a, b)$.

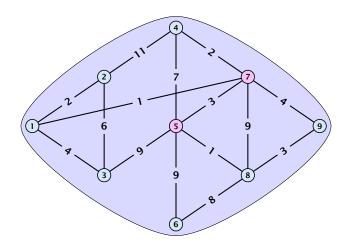

- Select S_i that contains at least two nodes a and b.
- Compute the connected components of the forest obtained from the current tree T after deleting S_i . Each of these components corresponds to a set of vertices from V.
- Consider the graph H obtained from G by contracting these connected components into single nodes.
- Compute a minimum a-b cut in H. Let A, and B denote the two sides of this cut.
- ▶ Split S_i in T into two sets/nodes $S_i^a = S_i \cap A$ and $S_i^b = S_i \cap B$ and add edge $\{S_i^a, S_i^b\}$ with capacity $f_H(a, b)$.
- ▶ Replace an edge $\{S_i, S_x\}$ by $\{S_i^a, S_x\}$ if $S_x \subset A$ and by $\{S_i^b, S_x\}$ if $S_x \subset B$.

$cap(X \cup S) + cap(S \cap X) \le cap(S) + cap(X)$

$cap(X \cup S) + cap(S \cap X) \le cap(S) + cap(X)$

Lemma 56 tells us that if we have a graph G = (V, E) and we contract a subset $X \subset V$ that corresponds to some mincut, then the value of f(s,t) does not change for two nodes $s,t \notin X$.

We will show (later) that the connected components that we contract during a split-operation each correspond to some mincut and, hence, $f_H(s,t)=f(s,t)$, where $f_H(s,t)$ is the value of a minimum s-t mincut in graph H.

Invariant [existence of representatives]:

For any edge $\{S_i, S_j\}$ in T, there are vertices $a \in S_i$ and $b \in S_j$ such that $w(S_i, S_j) = f(a, b)$ and the cut defined by edge $\{S_i, S_j\}$ is a minimum a-b cut in G.

We first show that the invariant implies that at the end of the algorithm T is indeed a cut-tree.

Let $s = x_0, x_1, \dots, x_{k-1}, x_k = t$ be the unique simple path from s to t in the final tree T. From the invariant we get that $f(x_i, x_{i+1}) = w(x_i, x_{i+1})$ for all j.

- Let $s = x_0, x_1, \dots, x_{k-1}, x_k = t$ be the unique simple path from s to t in the final tree T. From the invariant we get that $f(x_i, x_{i+1}) = w(x_i, x_{i+1})$ for all j.
- Then

$$f_T(s,t)$$

- Let $s = x_0, x_1, \dots, x_{k-1}, x_k = t$ be the unique simple path from s to t in the final tree T. From the invariant we get that $f(x_i, x_{i+1}) = w(x_i, x_{i+1})$ for all j.
- Then

$$f_T(s,t) = \min_{i \in \{0,\dots,k-1\}} \{w(x_i,x_{i+1})\}$$

- Let $s = x_0, x_1, \dots, x_{k-1}, x_k = t$ be the unique simple path from s to t in the final tree T. From the invariant we get that $f(x_i, x_{i+1}) = w(x_i, x_{i+1})$ for all j.
- Then

$$f_T(s,t) = \min_{i \in \{0,\dots,k-1\}} \{w(x_i,x_{i+1})\}$$
$$= \min_{i \in \{0,\dots,k-1\}} \{f(x_i,x_{i+1})\}$$

We first show that the invariant implies that at the end of the algorithm T is indeed a cut-tree.

- Let $s = x_0, x_1, \dots, x_{k-1}, x_k = t$ be the unique simple path from s to t in the final tree T. From the invariant we get that $f(x_i, x_{i+1}) = w(x_i, x_{i+1})$ for all j.
- Then

$$\begin{split} f_T(s,t) &= \min_{i \in \{0,\dots,k-1\}} \{w(x_i,x_{i+1})\} \\ &= \min_{i \in \{0,\dots,k-1\}} \{f(x_i,x_{i+1})\} \leq f(s,t) \ . \end{split}$$

237/242

We first show that the invariant implies that at the end of the algorithm T is indeed a cut-tree.

- Let $s = x_0, x_1, \dots, x_{k-1}, x_k = t$ be the unique simple path from s to t in the final tree T. From the invariant we get that $f(x_i, x_{i+1}) = w(x_i, x_{i+1})$ for all j.
- Then

$$\begin{split} f_T(s,t) &= \min_{i \in \{0,\dots,k-1\}} \{w(x_i,x_{i+1})\} \\ &= \min_{i \in \{0,\dots,k-1\}} \{f(x_i,x_{i+1})\} \leq f(s,t) \ . \end{split}$$

Let $\{x_i, x_{i+1}\}$ be the edge with minimum weight on the path.

We first show that the invariant implies that at the end of the algorithm T is indeed a cut-tree.

- Let $s = x_0, x_1, \dots, x_{k-1}, x_k = t$ be the unique simple path from s to t in the final tree T. From the invariant we get that $f(x_i, x_{i+1}) = w(x_i, x_{i+1})$ for all j.
- Then

$$\begin{split} f_T(s,t) &= \min_{i \in \{0,\dots,k-1\}} \{w(x_i,x_{i+1})\} \\ &= \min_{i \in \{0,\dots,k-1\}} \{f(x_i,x_{i+1})\} \leq f(s,t) \ . \end{split}$$

- Let $\{x_i, x_{i+1}\}$ be the edge with minimum weight on the path.
- Since by the invariant this edge induces an s-t cut with capacity $f(x_i, x_{i+1})$ we get $f(s, t) \le f(x_i, x_{i+1}) = f_T(s, t)$.

237/242

► Hence, $f_T(s,t) = f(s,t)$ (flow equivalence).

- ► Hence, $f_T(s,t) = f(s,t)$ (flow equivalence).
- ▶ The edge $\{x_j, x_{j+1}\}$ is a mincut between s and t in T.

- ► Hence, $f_T(s,t) = f(s,t)$ (flow equivalence).
- ▶ The edge $\{x_i, x_{i+1}\}$ is a mincut between s and t in T.
- By invariant, it forms a cut with capacity $f(x_j, x_{j+1})$ in G (which separates s and t).

- ► Hence, $f_T(s,t) = f(s,t)$ (flow equivalence).
- ▶ The edge $\{x_j, x_{j+1}\}$ is a mincut between s and t in T.
- ▶ By invariant, it forms a cut with capacity $f(x_j, x_{j+1})$ in G (which separates s and t).
- Since, we can send a flow of value $f(x_j, x_{j+1})$ btw. s and t, this is an s-t mincut (cut property).

The invariant obviously holds at the beginning of the algorithm.

The invariant obviously holds at the beginning of the algorithm.

Now, we show that it holds after a split-operation provided that it was true before the operation.

The invariant obviously holds at the beginning of the algorithm.

Now, we show that it holds after a split-operation provided that it was true before the operation.

Let S_i denote our selected cluster with nodes a and b. Because of the invariant all edges leaving $\{S_i\}$ in T correspond to some mincuts.

The invariant obviously holds at the beginning of the algorithm.

Now, we show that it holds after a split-operation provided that it was true before the operation.

Let S_i denote our selected cluster with nodes a and b. Because of the invariant all edges leaving $\{S_i\}$ in T correspond to some mincuts.

Therefore, contracting the connected components does not change the mincut btw. a and b due to Lemma 56.

The invariant obviously holds at the beginning of the algorithm.

Now, we show that it holds after a split-operation provided that it was true before the operation.

Let S_i denote our selected cluster with nodes a and b. Because of the invariant all edges leaving $\{S_i\}$ in T correspond to some mincuts.

Therefore, contracting the connected components does not change the mincut btw. a and b due to Lemma 56.

After the split we have to choose representatives for all edges. For the new edge $\{S_i^a, S_i^b\}$ with capacity $w(S_i^a, S_i^b) = f_H(a,b)$ we can simply choose a and b as representatives.

For edges that are not incident to S_i we do not need to change representatives as the neighbouring sets do not change.

For edges that are not incident to S_i we do not need to change representatives as the neighbouring sets do not change.

Consider an edge $\{X, S_i\}$, and suppose that before the split it used representatives $x \in X$, and $s \in S_i$. Assume that this edge is replaced by $\{X, S_i^a\}$ in the new tree (the case when it is replaced by $\{X, S_i^b\}$ is analogous).

For edges that are not incident to S_i we do not need to change representatives as the neighbouring sets do not change.

Consider an edge $\{X, S_i\}$, and suppose that before the split it used representatives $x \in X$, and $s \in S_i$. Assume that this edge is replaced by $\{X, S_i^a\}$ in the new tree (the case when it is replaced by $\{X, S_i^b\}$ is analogous).

If $s \in S_i^a$ we can keep x and s as representatives.

For edges that are not incident to S_i we do not need to change representatives as the neighbouring sets do not change.

Consider an edge $\{X, S_i\}$, and suppose that before the split it used representatives $x \in X$, and $s \in S_i$. Assume that this edge is replaced by $\{X, S_i^a\}$ in the new tree (the case when it is replaced by $\{X, S_i^b\}$ is analogous).

If $s \in S_i^a$ we can keep x and s as representatives.

Otherwise, we choose x and a as representatives. We need to show that f(x,a) = f(x,s).

Because the invariant was true before the split we know that the edge $\{X, S_i\}$ induces a cut in G of capacity f(x, s). Since, x and a are on opposite sides of this cut, we know that $f(x, a) \le f(x, s)$.

Because the invariant was true before the split we know that the edge $\{X,S_i\}$ induces a cut in G of capacity f(x,s). Since, x and a are on opposite sides of this cut, we know that $f(x,a) \le f(x,s)$.

The set B forms a mincut separating a from b. Contracting all nodes in this set gives a new graph G' where the set B is represented by node v_B . Because of Lemma 56 we know that f'(x,a) = f(x,a) as $x, a \notin B$.

Because the invariant was true before the split we know that the edge $\{X, S_i\}$ induces a cut in G of capacity f(x, s). Since, x and a are on opposite sides of this cut, we know that $f(x, a) \le f(x, s)$.

The set B forms a mincut separating a from b. Contracting all nodes in this set gives a new graph G' where the set B is represented by node v_B . Because of Lemma 56 we know that f'(x,a) = f(x,a) as $x,a \notin B$.

We further have $f'(x, a) \ge \min\{f'(x, v_B), f'(v_B, a)\}.$

Because the invariant was true before the split we know that the edge $\{X, S_i\}$ induces a cut in G of capacity f(x, s). Since, x and a are on opposite sides of this cut, we know that $f(x, a) \le f(x, s)$.

The set B forms a mincut separating a from b. Contracting all nodes in this set gives a new graph G' where the set B is represented by node v_B . Because of Lemma 56 we know that f'(x,a) = f(x,a) as $x,a \notin B$.

We further have $f'(x, a) \ge \min\{f'(x, v_B), f'(v_B, a)\}.$

Since $s \in B$ we have $f'(v_B, x) \ge f(s, x)$.

Because the invariant was true before the split we know that the edge $\{X, S_i\}$ induces a cut in G of capacity f(x, s). Since, x and a are on opposite sides of this cut, we know that $f(x, a) \le f(x, s)$.

The set B forms a mincut separating a from b. Contracting all nodes in this set gives a new graph G' where the set B is represented by node v_B . Because of Lemma 56 we know that f'(x,a) = f(x,a) as $x, a \notin B$.

We further have $f'(x, a) \ge \min\{f'(x, v_B), f'(v_B, a)\}.$

Since $s \in B$ we have $f'(v_B, x) \ge f(s, x)$.

Also, $f'(a, v_B) \ge f(a, b) \ge f(x, s)$ since the a-b cut that splits S_i into S_i^a and S_i^b also separates s and x.
