### 15 Global Mincut

Given an undirected, capacitated graph G = (V, E, c) find a partition of V into two non-empty sets  $S, V \setminus S$  s.t. the capacity of edges between both sets is minimized.

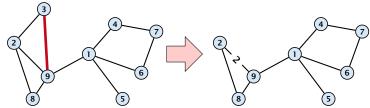

Ernst Mayr, Harald Räcke

22. Feb. 2020 135/150

# **Edge Contractions**

- Given a graph G = (V, E) and an edge  $e = \{u, v\}$ .
- The graph G/e is obtained by "identifying" u and v to form a new node.
- Resulting parallel edges are replaced by a single edge, whose capacity equals the sum of capacities of the parallel edges.

### **Example 6**

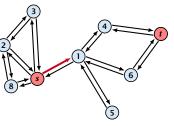

Edge-contractions do no decrease the size of the mincut.

### 15 Global Mincut

We can solve this problem using standard maxflow/mincut.

- Construct a directed graph G' = (V, E') that has edges (u, v) and (v, u) for every edge  $\{u, v\} \in E$ .
- Fix an arbitrary node  $s \in V$  as source. Compute a minimum s-t cut for all possible choices  $t \in V$ ,  $t \neq s$ . (Time:  $\mathcal{O}(n^4)$ )
- Let  $(S, V \setminus S)$  be a minimum global mincut. The above algorithm will output a cut of capacity  $cap(S, V \setminus S)$  whenever  $|\{s,t\} \cap S| = 1$ .

Ernst Mayr, Harald Räcke

15 Global Mincut

# **Edge Contractions**

We can perform an edge-contraction in time  $\mathcal{O}(n)$ .

137/150

# **Randomized Mincut Algorithm**

### **Algorithm 1** KargerMincut(G = (V, E, c))

- 1: **for**  $i = 1 \rightarrow n 2$  **do**
- choose  $e \in E$  randomly with probability c(e)/c(E)
- $G \leftarrow G/e$
- 4: **return** only cut in *G*
- Let  $G_t$  denote the graph after the (n-t)-th iteration, when t nodes are left.
- ▶ Note that the final graph  $G_2$  only contains a single edge.
- $\blacktriangleright$  The cut in  $G_2$  corresponds to a cut in the original graph Gwith the same capacity.
- ▶ What is the probability that this algorithm returns a mincut?

# **Example: Randomized Mincut Algorithm**

15 Global Mincut

140/150

# **Analysis**

### What is the probability that a given mincut A is still possible after round i?

lt is still possible to obtain cut A in the end if so far no edge in  $(A, V \setminus A)$  has been contracted.

### **Analysis**

### What is the probability that we select an edge from A in iteration i?

- Let  $min = cap(A, V \setminus A)$  denote the capacity of a mincut.
- $\blacktriangleright$  Let cap(v) be capacity of edges incident to vertex  $v \in V_{n-i+1}$ .
- ightharpoonup Clearly, cap(v)  $\geq$  min.

Ernst Mayr, Harald Räcke

ightharpoonup Summing cap(v) over all edges gives

$$2c(E) = 2\sum_{e \in E} c(e) = \sum_{v \in V} \operatorname{cap}(v) \ge (n - i + 1) \cdot \min$$

▶ Hence, the probability of choosing an edge from the cut is at most min  $/c(E) \le 2/(n-i+1)$ .

n-i+1 is the number of nodes in graph  $G_{n-i+1} = (V_{n-i+1}, E_{n-i+1})$ , the graph at the start of iteration i.

# **Analysis**

The probability that we do not choose an edge from the cut in iteration i is

$$1 - \frac{2}{n-i+1} = \frac{n-i-1}{n-i+1} .$$

The probability that the cut is alive after iteration n-t (after which t nodes are left) is at most

$$\prod_{i=1}^{n-t} \frac{n-i-1}{n-i+1} = \frac{t(t-1)}{n(n-1)} .$$

Choosing t=2 gives that with probability  $1/\binom{n}{2}$  the algorithm computes a mincut.

| | | Ernst Mayr, Harald Räcke

15 Global Mincut

143/150

# **Analysis**

Repeating the algorithm  $c \ln n \binom{n}{2}$  times gives that the probability that we are never successful is

$$\left(1 - \frac{1}{\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le \left(e^{-1/\binom{n}{2}}\right)^{\binom{n}{2}c\ln n} \le n^{-c} ,$$

where we used  $1 - x \le e^{-x}$ .

#### Theorem 7

The randomized mincut algorithm computes an optimal cut with high probability. The total running time is  $O(n^4 \log n)$ .

# **Improved Algorithm**

### **Algorithm 2** RecursiveMincut(G = (V, E, c))

1: **for** 
$$i = 1 \rightarrow n - n/\sqrt{2}$$
 **do**

choose  $e \in E$  randomly with probability c(e)/c(E)

3: 
$$G \leftarrow G/e$$

4: **if** |V| = 2 **return** cut-value;

5: *cuta* ← RecursiveMincut(G);

6: *cutb* ← RecursiveMincut(G);

7: **return** min{*cuta*, *cutb*}

### Running time:

- $T(n) = 2T\left(\frac{n}{\sqrt{2}}\right) + \mathcal{O}(n^2)$
- ▶ This gives  $T(n) = \mathcal{O}(n^2 \log n)$ .

Note that the above implementation only works for very special values of n.

15 Global Mincut

144/150

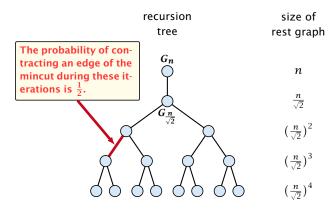

# **Probability of Success**

The probability of not contracting an edge from the mincut during one iteration through the for-loop is at least

$$\frac{t(t-1)}{n(n-1)} \ge \frac{t^2}{n^2} = \frac{1}{2} ,$$

as 
$$t = \frac{n}{\sqrt{2}}$$
.

# **Probability of Success**

We can estimate the success probability by using the following game on the recursion tree. Delete every edge with probability  $\frac{1}{2}$ . If in the end you have a path from the root to at least one leaf node you are successful.

15 Global Mincut

147/150

149/150

# **Probability of Success**

### Proof.

- ▶ An edge e with h(e) = 1 is alive if and only if it is not deleted. Hence, it is alive with proability at least  $\frac{1}{2}$ .
- Let  $p_d$  be the probability that an edge e with h(e) = d is alive. For d > 1 this happens for edge  $e = \{c, p\}$  if it is not deleted **and** if one of the child-edges connecting to *c* is alive.
- ► This happens with probability

$$p_{d} = \frac{1}{2} \left( 2p_{d-1} - p_{d-1}^{2} \right) \left[ \Pr[A \vee B] = \Pr[A] + \Pr[B] - \Pr[A \wedge B] \right]$$

$$= p_{d-1} - \frac{p_{d-1}^{2}}{2}$$

$$x - x^2/2$$
 is monotonically increasing for  $x \in [0, 1]$ 

## **Probability of Success**

Let for an edge e in the recursion tree, h(e) denote the height (distance to leaf level) of the parent-node of *e* (end-point that is higher up in the tree). Let h denote the height of the root node.

Call an edge e alive if there exists a path from the parent-node of e to a descendant leaf, after we randomly deleted edges. Note that an edge can only be alive if it hasn't been deleted.

#### Lemma 8

The probability that an edge e is alive is at least  $\frac{1}{h(e)+1}$ .

15 Global Mincut

148/150

### 15 Global Mincut

#### Lemma 9

One run of the algorithm can be performed in time  $O(n^2 \log n)$ and has a success probability of  $\Omega(\frac{1}{\log n})$ .

Doing  $\Theta(\log^2 n)$  runs gives that the algorithm succeeds with high probability. The total running time is  $\mathcal{O}(n^2 \log^3 n)$ .
